KEYWORDS
Free vibration of postbuckled nanocomposite annular plate; Postbuckling behavior; Carbon nanotube-reinforced composites; Numerical approach; GDQ method.

Abstract. This paper studies the free vibration characteristics of post-buckled Functionally Graded (FG) carbon nanotube (CNT) reinforced annular plates. The analysis was performed by employing a Generalized Differential Quadrature (GDQ) type numerical technique and pseudo-arc length scheme. The material properties of FG-carbon nanotube reinforced composite (CNTC) plates were evaluated by an equivalent continuum approach based on the modified rule of mixture. The vibration problem was formulated based on the First-order Shear Deformation Theory (FSDT) for moderately thick laminated plates and von Kármán nonlinearity. By employing Hamilton’s principle and a variational approach, the nonlinear equations and associated Boundary Conditions (BCs) were derived, which were then discretized by the GDQ method. The postbuckling behavior was investigated by plotting the secondary equilibrium path as the deflection-load curves. Thereafter, the free vibration behaviors of pre- and post-buckled FG-CNTC annular plates were examined. Effects of different parameters including types of BCs, CNT volume fraction, an outer radius-to-thickness ratio, and an inner-to-outer radius ratio were investigated in detail.

1. Introduction

Since the discovery of carbon nanotubes (CNTs) by Iijima in 1991 [1], considerable advances have been made in the realm of nanotechnology. CNTs are the most extraordinary materials that have been discovered by mankind over the past thirty years. Characterized by extraordinary properties, they have attracted a great deal of attention from the scientific community and beyond [2-5]. These materials have the potential to revolutionize different fields such as medicine, electronics, material science, energy storage, etc. CNTs are reported to enjoy many desired properties such as high tensile strength and Young’s modulus. The high strength of CNTs makes them the stiffest known fiber discovered so far. Further, CNTs enjoy excellent thermal and electrical conducting properties and can either show metallic or semi-conducting behavior based on their size, chirality, and purity. Thus, CNTs can be used as reinforcements to enhance the physical and mechanical properties and electrical conductivity of the polymeric structures. Because of some characteristics such as wear and corrosion resistance, low density, light weight, and low cost, polymer-based composites are extensively utilized in the industrial and

engineering usages including marine and automotive technologies, military, and the agricultural industry [6]. The addition of CNTs to polymers may result in the enhancement of many mechanical, electrical, and optical properties of polymer-based nanocomposites. These superior properties make them the best candidate for use in various usages such as actuators, biomedical devices, chemical sensors, and smart memory devices [7,8]. Ajayan et al. [9] fabricated carbon nanotube reinforced composites (CNTCs) for the first time in 1994. Since then, a number of studies have been performed to utilize CNTs as reinforcement for various materials such as polymer, ceramic, and metals. For instance, Hassanzadeh-Aghdam and Mahmoodi [10] conducted a comprehensive analysis of the mechanical properties of CNT-reinforced metallic nanocomposites by proposing an analytical approach. The effects of CNT volume fraction, interphase, and geometry on the thermal expansion behavior of CNT-reinforced metallic composites were studied by Hassanzadeh-Aghdam et al. [11,12]. Foroughi et al. [13] experimentally examined the influence of CNTs on the mechanical and bioactive properties of bioglass-ionomer cement. Moreover, AfsarTabar et al. [14] investigated the CNTs and nano-porous graphene on the silica nanohybrid Pickering emulsion. Recently, Rafiee et al. [15] experimentally studied the vibrational and damping behaviors of functionalized multi-walled CNT-reinforced epoxy nanocomposites as the passive damping components. 

Among the published papers on the mechanical characteristics of CNT-reinforced composites, the majority have been devoted to the reinforcement of polymers by CNTs [16-24]. This is because of the relative ease of polymer processing, which demands lower temperatures for consolidation compared to metals and ceramic matrix composites. The fascinating mechanical properties of CNTs over carbon fibers have resulted in increasing use of CNT-reinforced composite structures. The main difference between these two types of composites lies in the low quantity of CNTs used in the CNTRCs [25-27]. Meguid and Sun [28] stated that by increasing the CNT volume fraction beyond a specified limit, the mechanical properties of CNTRCs will deteriorate. As a result, the concept of Functionally Graded (FG) materials has been incorporated in the modeling of CNTRCs in order to use CNTs more efficiently in the reinforced composites. The local buckling of CNTRC beams induced by the bending was studied by Vodenitcharov and Zhang [29]. The imperfection sensitivity of the primary resonances of FG-CNTRC beams under periodic transverse loading was examined by Ghobadi et al. [30]. A Mori-Tanaka based equivalent model was utilized by Forinika et al. [31] to study the free vibration of CNTRC plates. Their study showed that the maximum enhancement of the properties of fiber composites was obtainable by uniformly aligning CNTs with the loading direction. Ansari et al. [32] examined the nonlinear forced vibration of Timoshenko beams made of FG-CNTRCs. Shen and He [33] studied the nonlinear vibration of embedded FG-CNTRC curved panels under thermal loading. It was found that nonlinear vibration behavior of CNTRC panels was considerably affected by the FG-CNTRC reinforcements. The nonlinear forced vibration of FG-CNTRC rectangular plates based upon Mindlin and Reddy’s plate theories was analyzed by Ansari et al. [34,35]. In addition, Ansari et al. [36] analytically studied the postbuckling of piezoelectric FG-CNTRC shells. Lin and Xiang [37] investigated the free vibrational characteristics of SWCNT-reinforced nanocomposite beams. The variational technique of Hamilton’s principle and sense of von Kármán’s nonlinearity were used to derive the energies of the CNT-reinforced composite beams. Then, by employing the p-Ritz technique, the free vibration problem of the beam was solved. The free vibration of FG-CNTRC cylindrical shells under the thermal loading was analyzed by Song et al. [38] upon employing the assumed modes approach. Mehrabadi et al. [39] examined linear buckling of FG-CNTRC plates under uniaxial and biaxial compression. In a study conducted by Liu et al. [40], free vibrations of SWCNT-reinforced nanocomposite plates were analyzed by the kp-Ritz method. Shen et al. [41] presented a study on the vibrational response of thermally postbuckled sandwich CNTRC plates resting on the elastic mediums. Ahmadi et al. [42] employed a multi-scale finite element procedure to obtain the mechanical properties of carbon fiber-CNT-polyimide nanocomposites and, then, examine the buckling of rods made of these nanocomposites. Recently, according to a variational approach, Ghobaci and Ansari [43] provided a weak form of mathematical modeling to study the nonlinear resonant responses of shear deformable FG-CNTRC annular sector plates. In addition, the resonance of multi-scale laminated nanocomposite rectangular plates was examined by Ghobachi et al. [44]. According to the First-order Shear Deformation Theory (FSDT) and Rayleigh-Ritz scheme, the free vibration of nanocomposite spherical panels and shells of revolution was studied by Wang et al. [45].

In this work, upon employing the Generalized Differential Quadrature (GDQ) approach, the free vibration problem of postbuckled FG-CNTRC annular plates with Uniformly Distributed (UD) and FG reinforcements is numerically formulated. It is assumed that the material properties of FG-CNTRCs are obtained by employing a modified rule of mixture-based equivalent model. The postbuckling problem is formulated on the basis of the FSDT with a von Kármán type of kinematic nonlinearity. By applying Hamilton’s principle, the nonlinear equations and corresponding
BCs are derived and, then, discretized by the GDQ method. In addition, pseudo-arc length algorithm is employed to find the secondary equilibrium paths of CNTRCs plates. The free vibration of postbuckled CNTRC annular plates is formulated as a standard linear eigenvalue problem. Impacts of design parameters including type of BCs, CNT volume fraction, inner-to-outer radius ratio, and outer radius-to-thickness ratio on the equilibrium postbuckling path and fundamental frequencies in the pre- and post-buckled configurations are investigated.

2. Mathematical formulation

2.1. CNTRCs and material properties

As illustrated in Figure 1, an SWCNT-reinforced composite annular plate with inner radius, \( a \), outer radius, \( b \), and thickness, \( h \), is assumed. It is considered that the SWCNT reinforcements are UD or FG through the thickness. The structure of the CNT significantly affects the properties of the nanocomposites. Thus far, different micromechanical models such as the Mori-Tanaka [46,47] and Voigt models, as well as the rule of the mixture [26,48], have been proposed to obtain the material properties of CNTRCs. The former is used for micro-particles and the latter extensively for the CNTRCs. On a nanoscale, both of these approaches should be extended to capture the small-scale effect. It has been demonstrated that both of Mori-Tanaka and Voigt techniques have an identical level of accuracy in treating the static and dynamic problems of FG ceramic-metal beams [49], plates [50], and shells [51]. Accordingly, applying the modified version of the rule of mixture, one can express the effective Young’s and shear modulus of CNTRCs as follows [48]:

\[
E_{11} = \eta_1 V_{\text{cnt}} E_{11}^\text{cnt} + V_m E_m, \quad (1a)
\]

\[
\frac{\eta_2}{E_{22}} = \frac{V_{\text{cnt}}}{E_{22}^\text{cnt}} + \frac{V_m}{E_m}, \quad (1b)
\]

\[
\frac{\eta_3}{G_{12}} = \frac{V_{\text{cnt}}}{G_{12}^\text{cnt}} + \frac{V_m}{G_m}. \quad (1c)
\]

By considering this point that, through the formulations, sub-/super-scripts “\( m \)” and “\( \text{cnt} \)” signify the matrix and CNT, respectively, in Eq. (1), \( G \) and \( E \) represent shear and Young’s modulus, and \( \eta_j \) \((j = 1, 2, 3)\) identifies the CNT efficiency parameter, which is attributed to the scale-dependent properties. It is notable that \( \eta_j \) will be later obtained by matching the material properties achieved from the Molecular Dynamics (MD) simulations with those obtained from the rule of mixture. In addition, \( V_{\text{cnt}} \) and \( V_m \) denote the volume fractions of CNT and matrix, respectively, and have the following relationship as follows:

\[
V_{\text{cnt}} + V_m = 1. \quad (2)
\]

The FG-CNTRCs are supposed to be in two different configurations, namely O and X types. For convenience, in the following, the two types of FG-CNTRCs are indicated by FGO and FGX. For the case, the FG-CNTRC is referred to as FGO, and the middle surface of the composite is CNT-rich, while, for the FGX, both outer and inner faces are CNT-rich. In this study, the UD, FGO, and FGX distributions of CNTs are of special concern and are expressed as below [48]:

\[
\text{UD} : V_{\text{cnt}} = V_{\text{cnt}}^*, \quad (3a)
\]

\[
\text{FGO} : V_{\text{cnt}} = 2 \left(1 - \frac{2h}{l}\right) V_{\text{cnt}}^*, \quad (3b)
\]

\[
\text{FGX} : V_{\text{cnt}} = \frac{4l}{h} V_{\text{cnt}}^*. \quad (3d)
\]

where:

\[
V_{\text{cnt}}^* = \frac{\Lambda_{\text{cnt}}}{\Lambda_{\text{cnt}} + \left(\frac{\rho_{\text{cnt}}}{\rho_m}\right) - \left(\frac{\rho_{\text{cnt}}}{\rho_m}\right)\Lambda_{\text{cnt}}}. \quad (4)
\]

In the preceding equation, \( \Lambda_{\text{cnt}} \) is the mass fraction of CNT, and \( \rho \) denotes the mass density. Similar to the previous case, effective Poisson’s ratios \( \nu \) and \( \rho \) are obtained by Wang and Shen [52]:

\[
\nu_{12} = V_{\text{cnt}}\nu_{12}^\text{cnt} + V_m \nu_m, \quad \nu_{21} = \nu_{12} E_{22}/E_{11}, \quad (5)
\]

\[
\rho = V_{\text{cnt}}\rho_{\text{cnt}} + V_m \rho_m. \quad (6)
\]
2.2. Nonlinear equations of motion and corresponding BCs

Consider a cylindrical coordinate system \((r, \theta, z)\) in which its origin is placed at the center of the midplane of the FG-CNTRC annular plate, and \(r, \theta,\) and \(z\)-axes denote radial, tangential, and thickness directions, respectively. Considering the axisymmetric deformation, the displacement components, \(u_r, u_\theta\) and \(u_z\) along \(r, \theta,\) and \(z\)-axes, respectively, are obtained by Liew et al. [53]:

\[
u_r = u(t, r) + z\psi_r(t, r), \quad u_\theta = u(t, r), \quad u_z = w(t, r),
\]

where \(u(t, r)\) and \(w(t, r)\) are the radial and transverse displacement components of middle-plane, respectively, and \(\psi_r(t, r)\) is the rotation about \(\theta\)-axis. In addition, \(t\) denotes time. Of note, the displacement field defined in Eq. (7) is based on the FSDT.

By applying Eq. (7), the strain-displacement relations are expressed by:

\[
\varepsilon_r = \frac{\partial u}{\partial r} + \frac{1}{2} \left( \frac{\partial w}{\partial r} \right)^2 + z \frac{\partial \psi_r}{\partial r}, \quad \varepsilon_\theta = \frac{u}{r} + \frac{\psi_r}{r}, \quad \varepsilon_z = \psi_r r.
\]

Additionally, according to the linear elasticity and the von Kármán hypothesis, the nonlinear stress components can be defined by:

\[
\begin{align*}
\{ \sigma_r \} & = \begin{bmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{55} \end{bmatrix} \{ \varepsilon_r \}, \\
\{ \sigma_\theta \} & = \begin{bmatrix} \varepsilon_r \\ \varepsilon_\theta \\ \varepsilon_z \end{bmatrix},
\end{align*}
\]

where:

\[
\begin{align*}
Q_{11} & = \frac{E_{11}}{1 - \nu_{12} \nu_{21}}, & Q_{22} & = \frac{E_{22}}{1 - \nu_{12} \nu_{21}}, \\
Q_{12} & = \frac{\nu_{21} E_{11}}{1 - \nu_{12} \nu_{21}}, & Q_{55} & = G_{13}.
\end{align*}
\]

In the previous equation, parameters \(E_{ij}, G_{ij},\) and \(\nu_{ij}\) are obtained through Eqs. (1) and (5).

Based on the previous discussion, now, the in-plane force resultants \((N_r, N_\theta)\), moment resultants \((M_r, M_\theta)\), and transverse force resultant \((Q_r)\) are obtained by:

\[
N = \begin{bmatrix} N_r \\ N_\theta \end{bmatrix} = \frac{1}{h/2} \int_{-h/2}^{h/2} \{ \sigma_r \} dz,
\]

\[
M = \begin{bmatrix} M_r \\ M_\theta \end{bmatrix} = \frac{1}{h/2} \int_{-h/2}^{h/2} \{ \sigma_\theta \} dz,
\]

\[
Q_r = \kappa_s \int_{-h/2}^{h/2} \sigma_r dz,
\]

where \(\kappa_s = \pi^2/12\) denotes the shear correction factor [53]. By inserting Eqs. (9) and (10) into Eq. (11), one obtains:

\[
N_r = A_{11} \left[ \frac{\partial u}{\partial r} + \frac{1}{2} \left( \frac{\partial w}{\partial r} \right)^2 \right] + A_{12} \frac{u}{r} + B_{11} \frac{\partial \psi_r}{\partial r} + B_{12} \psi_r r,
\]

\[
N_\theta = A_{22} \frac{u}{r} + A_{12} \left[ \frac{\partial u}{\partial r} + \frac{1}{2} \left( \frac{\partial w}{\partial r} \right)^2 \right] + B_{22} \psi_r r + B_{12} \frac{\partial \psi_r}{\partial r},
\]

\[
M_r = B_{11} \left[ \frac{\partial u}{\partial r} + \frac{1}{2} \left( \frac{\partial w}{\partial r} \right)^2 \right] + B_{12} \frac{u}{r} + D_{11} \frac{\partial \psi_r}{\partial r} + D_{12} \psi_r r,
\]

\[
M_\theta = B_{22} \frac{u}{r} + B_{12} \left[ \frac{\partial u}{\partial r} + \frac{1}{2} \left( \frac{\partial w}{\partial r} \right)^2 \right] + D_{22} \psi_r r + D_{12} \frac{\partial \psi_r}{\partial r},
\]

\[
Q_r = k_s A_{55} \left( \psi_r + \frac{\partial w}{\partial r} \right),
\]

where:

\[
(A_{ij}, B_{ij}, D_{ij}) = \int_{-h/2}^{h/2} Q_{ij} \{ 1, z, z^2 \} dz; \quad (i, j = 1, 2),
\]

\[
A_{ij} = \int_{-h/2}^{h/2} Q_{ij} dz; \quad (i, j = 5).
\]

The strain energy (\(\Pi_r\)) expression for the FG-CNTRC annular plates takes the following form:

\[
\Pi_r = \frac{1}{2} \int_{S} \int_{-h/2}^{h/2} \sigma_r \varepsilon_r dz dS
\]

\[
= \frac{1}{2} \int_{S} \left\{ N_r \left[ \frac{\partial u}{\partial r} + \frac{1}{2} \left( \frac{\partial w}{\partial r} \right)^2 \right] + N_\theta \frac{u}{r} + M_r \frac{\partial \psi_r}{\partial r} + M_\theta \psi_r r + Q_r \left( \psi_r + \frac{\partial w}{\partial r} \right) \right\} dS,
\]

where \(S\) denotes the plate area. The kinetic energy, \(\Pi_T\), and the potential energy, \(\Pi_{\text{p}}\), resulting from the applied external radial load, \(N_r\), are expressed by:
\[ \Pi_T = \frac{1}{2} \int \left[ I_0 \left( \left( \frac{\partial u}{\partial t} \right)^2 + \left( \frac{\partial w}{\partial t} \right)^2 \right) + 2I_1 \frac{\partial u}{\partial t} \frac{\partial w}{\partial t} + I_2 \left( \frac{\partial \psi}{\partial t} \right)^2 \right] dS, \] 

\[ \Pi_w = \int \left[ \frac{1}{2} N_0^2 \left( \frac{\partial w}{\partial t} \right)^2 \right] dS. \]

Using Hamilton's principle \[54]:

\[ \int_{t_1}^{t_2} \left( \delta \Pi_T - \delta \Pi_I + \delta \Pi_w \right) dt = 0, \] 

where \( \delta \) denotes the variation operator; one can achieve the governing equations and all possible BCs. By inserting Eqs. (14) and (15) into (16), taking the variation of \( u, w, \) and \( \psi \), through the integration by parts, and lastly by equating the coefficients of \( \delta u, \delta w, \) and \( \delta \psi \), to zero, the following expressions are obtained for the governing equations of motion (Eqs. (17a)-(17c)) and the BCs (Eqs. (18a)-(18c))

\[ \frac{\partial \delta N_r}{\partial \theta} + \frac{N_r - N_0}{r} = I_0 \frac{\partial \delta u}{\partial \theta} + I_1 \frac{\partial \delta \psi}{\partial \theta}, \] 

\[ \frac{\partial \delta Q_r}{\partial \theta} + \frac{Q_r}{r} + \frac{1}{r} \frac{\partial}{\partial \theta} \left( r N_r \frac{\partial u}{\partial \theta} \right) + N_0^2 \left( \frac{\partial \delta w}{\partial \theta} + \frac{1}{r} \frac{\partial \delta w}{\partial \theta} \right) = I_0 \frac{\partial \delta w}{\partial \theta}, \] 

\[ \frac{\partial \delta M_r}{\partial \theta} + \frac{M_r - M_0}{r} = Q_r = I_2 \frac{\partial \delta \psi}{\partial \theta} + I_1 \frac{\delta \psi}{\partial \theta}, \]

and:

\[ \delta u = 0 \quad \text{or} \quad N_r = 0, \] 

\[ \delta w = 0 \quad \text{or} \quad (N_r + N_0^0 \frac{\partial \psi}{\partial \theta} + Q_r = 0, \] 

\[ \delta \psi = 0 \quad \text{or} \quad M_r = 0. \]

By inserting Eq. (12) into Eqs. (17), the governing equations are determined in terms of displacement components as follows:

\[ A_{11} \left[ \frac{\partial^2 \delta u}{\partial \theta^2} + \frac{1}{r} \frac{\partial \delta u}{\partial \theta} + \frac{\partial \delta w}{\partial \theta} + \frac{1}{2r} \left( \frac{\partial \delta w}{\partial \theta} \right)^2 \right] + B_{11} \left( \frac{\partial^2 \delta \psi}{\partial \theta^2} + \frac{1}{r} \frac{\partial \delta \psi}{\partial \theta} \right) - A_{22} \frac{u}{r^2} \]

\[ - B_{22} \frac{\psi}{r^2} - A_{12} \frac{\partial \psi}{\partial \theta} = I_0 \frac{\partial \delta u}{\partial \theta} + I_1 \frac{\delta \psi}{\partial \theta}, \] 

where:

\[ N(w) = \left\{ A_{11} \left[ \frac{\partial u}{\partial \theta} + \frac{1}{2} \left( \frac{\partial u}{\partial \theta} \right)^2 \right] + A_{12} \frac{u}{r} + B_{11} \frac{\partial \psi}{\partial \theta} + B_{22} \psi \right\} \left( \frac{1}{r} \frac{\partial \delta w}{\partial \theta} + \frac{\partial \delta w}{\partial \theta} \right) \] 

\[ + A_{12} \frac{\delta u}{\partial \theta} \frac{\partial \delta \psi}{\partial \theta} + \frac{B_{22}}{2r} \left( \frac{\partial \delta \psi}{\partial \theta} \right)^2 \]

\[ + \left\{ A_{11} \left( \frac{\partial \delta u}{\partial \theta} + \frac{\partial \delta w}{\partial \theta} \right) \right\} \]

The BCs provided in Eq. (18) show the possible edge conditions for the FG-CNTRC annular plates. Consequently, the BCs are as follows:

For the simply supported CNTRC annular plates:

\[ N_r = w = M_r = 0. \] 

For clamped CNTRC annular plates:

\[ N_r = w = \psi = 0. \] 

The following dimensionless quantities are introduced so as to non-dimensionalize the governing equations of motion:

\[ \xi = \frac{r}{b}, \quad \eta = \frac{b}{h}, \quad \{u, w\} \rightarrow h \{u, w\}, \]

\[ \psi = \psi_r, \quad N_0^0 = \frac{N_r}{A_{110}}, \quad \tau = \frac{t}{b} \sqrt{\frac{A_{110}}{I_{10}}}, \]

\[ \{a_{11}, a_{22}, a_{12}, a_{55}\} = \frac{\{A_{11}, A_{22}, A_{12}, A_{55}\}}{A_{110}}. \]
\[ \{ d_{11}, d_{12}, d_{32}, d_{53} \} = \left( \frac{D_{11}, D_{12}, D_{12}}{A_{110} h^2} \right) , \]
\[ \{ I_0, I_1, I_2 \} = \left\{ \frac{I_0}{I_{100}}, I_1, \frac{I_2}{I_{200} h^2} \right\} , \]

where \( A_{120} \) and \( I_{100} \) show the values of \( A_{11} \) and \( I_0 \) for a homogeneous matrix plate. Thus, one obtains:

\[ a_{11} \left[ \frac{\partial^2 u}{\partial \xi^2} + \frac{1}{\xi} \frac{\partial u}{\partial \xi} + \frac{1}{\eta} \frac{\partial w}{\partial \xi} + \frac{1}{\eta^2} \frac{\partial w}{\partial \xi} \right] + \frac{b_{11}}{2 \eta} \frac{\partial^2 u}{\partial \xi^2} + b_{22} \frac{\partial u}{\partial \xi} = u \frac{\partial u}{\partial \xi} + 2 \xi \frac{\partial^2 u}{\partial \xi^2} \]

\[ + b_{22} \frac{\partial u}{\partial \xi} - b_{22} \xi^2 \]

\[ = L_0 \frac{\partial^2 \psi_r}{\partial \eta^2} + I_1 \frac{\partial^2 u}{\partial \xi^2} , \tag{23a} \]

\[ k, \alpha_{50} \left( \frac{\partial^2 w}{\partial \xi^2} + \frac{1}{\xi} \frac{\partial w}{\partial \xi} + \frac{\partial \psi_r}{\partial \xi} + \frac{\partial \psi_r}{\partial \xi} \right) + a_{11} \left[ \frac{\partial^2 u}{\partial \xi^2} + \frac{1}{\xi} \frac{\partial u}{\partial \xi} + \frac{1}{\eta} \frac{\partial w}{\partial \xi} + \frac{1}{\eta^2} \frac{\partial w}{\partial \xi} \right] \]

\[ + \frac{b_{11}}{2 \eta} \frac{\partial^2 u}{\partial \xi^2} + b_{12} \frac{\partial w}{\partial \xi} = \frac{1}{\xi} \frac{\partial \psi_r}{\partial \xi} + \frac{1}{\eta} \frac{\partial \psi_r}{\partial \xi} + \frac{1}{\eta^2} \frac{\partial \psi_r}{\partial \xi} \]

\[ + a_{11} \left[ \frac{\partial^2 u}{\partial \xi^2} + \frac{1}{\xi} \frac{\partial u}{\partial \xi} + \frac{1}{\eta} \frac{\partial w}{\partial \xi} + \frac{1}{\eta^2} \frac{\partial w}{\partial \xi} \right] \]

\[ + \frac{b_{11}}{2 \eta} \frac{\partial^2 u}{\partial \xi^2} + b_{12} \frac{\partial w}{\partial \xi} = \frac{1}{\xi} \frac{\partial \psi_r}{\partial \xi} + \frac{1}{\eta} \frac{\partial \psi_r}{\partial \xi} + \frac{1}{\eta^2} \frac{\partial \psi_r}{\partial \xi} \]

\[ = L_0 \frac{\partial^2 \psi_r}{\partial \eta^2} + I_0 \frac{\partial^2 u}{\partial \xi^2} , \tag{23b} \]

Further, by non-dimensionalizing the BCs, the following expressions are obtained for the simply supported (Eq. (24a)) and clamped (Eq. (24b)) BCs:

\[ a_{11} \left[ \frac{\partial \psi_r}{\partial \xi} + \frac{1}{2 \eta} \left( \frac{\partial \psi_r}{\partial \xi} \right)^2 \right] + a_{12} \frac{\partial^2 \psi_r}{\partial \xi^2} + b_{11} \frac{\partial \psi_r}{\partial \xi} = w = 0, \tag{24a} \]

\[ b_{11} \left[ \frac{\partial \psi_r}{\partial \xi} + \frac{1}{2 \eta} \left( \frac{\partial \psi_r}{\partial \xi} \right)^2 \right] + b_{12} \frac{\partial \psi_r}{\partial \xi} = w = 0, \tag{24b} \]

3. GDQ method

The GDQ method as an efficient numerical approach can be utilized for solving the boundary value problems including the ordinary and partial differential equations. Unlike the finite element method that is usually employed for solving the weak form of equations, the GDQ technique represents a powerful tool for solving the equations in the strong form with great efficiency and accuracy using a small number of discrete mesh points [55].

3.1. Introduction

With the aid of the GDQ technique [56-58], the pth order derivative of \( g(r) \) is attained in the following form:

\[ \frac{\partial^p g(y)}{\partial y^p} \bigg|_{y=r_j} = \sum_{j=1}^{N} A_{ij} g(r_j) , \tag{25} \]

where \( N \) is the number of total discrete points. By considering a column vector \( \mathbf{F} \):

\[ \mathbf{F} = [g] = [g(r_j)] = [g(r_1), g(r_2), \ldots, g(r_N)]^T , \tag{26} \]

where \( g_j = g(r_j) \) indicates the amount of \( g(r) \) at \( r_j \), and an operational matrix of differentiation on the basis of Eq. (25) is achieved as in the following form:

\[ \frac{\partial^p}{\partial y^p} (\mathbf{F}) = \mathbf{D}_p^p \mathbf{F} = [D_{ij}^p] \{ F_j \} , \tag{27} \]

where:

\[ \mathbf{D}_p^p = [D_{ij}^p] , \quad i, j = 1 : N ; \tag{28} \]

where \( A_{ij} \) gives the weighting coefficients obtained as by Eq. (29) as shown in Box I, in which \( \mathcal{P}(r_j) = P_{1j}^N + 1 \leq j \leq N \), and \( \mathbf{I} \) denotes an \( N \times N \) identity matrix.
\[
A^p_{ij} = \begin{cases} 
I_r, & r = 0 \\
\frac{p(r)}{(r_j - r_i)} & i \neq j \text{ and } i, j = 1, \ldots, N \text{ and } p = 1 \\
p \left( A^1_{ij} A^{p-1}_{ji} - \frac{A^p_{ji}}{r_i - r_j} \right), & i \neq j \text{ and } i, j = 1, \ldots, N \text{ and } p = 2, 3, \ldots N - 1 \\
- \sum_{j=1; j \neq i}^{N} A^p_{ij}, & i = j \text{ and } i, j = 1, \ldots, N \text{ and } p = 1, 2, 3, \ldots N - 1
\end{cases}
\]  

(29)

Box I

3.2. Postbuckling analysis

With the aid of Chebyshev-Gauss-Lobatto points as the grid points, the mesh generation can be obtained by:

\[
\xi_i = \alpha + \frac{1 - \alpha}{2} \left( 1 - \cos \frac{i - 1}{N - 1} \pi \right), i = 1 : N,
\]

(30)

where \( \alpha = a/b \). The discretized form of displacement components is defined as the following vectors:

\[
U^T = [U_1, \ldots , U_N],
\]

\[
W^T = [W_1, \ldots , W_N],
\]

\[
\Psi^T = [\Psi_1, \ldots , \Psi_N],
\]

(31)

where \( U_i = u(\xi_i) \), \( W_i = w(\xi_i) \), \( \Psi_i = \psi(\xi_i) \). By assuming \( N_e = -P \), utilizing the GDQ scheme, and discarding the inertia terms, the equilibrium equations are discretized by:

\[
a_{11} \left[ D^2_\xi U + D^2_\xi U \circ A_1 + \frac{1}{\eta} (D^2_\xi W) \circ (D^2_\xi W) \right] + \frac{1}{2 \eta} (D^2_\Psi U) \circ (D^2_\Psi W) \circ A_1 + b_{11} (D^2_\Psi U \circ A_1) - a_{22} U \circ A_2
\]

\[+ b_{22} \psi \circ A_2 - \frac{a_{12}}{2 \eta} (D^2_\Psi W) \circ (D^2_\Psi W) \circ A_1 = 0, \quad \text{(32a)}\]

\[+ \eta \left[ a_{11} \left( D^2_\xi U + \frac{1}{2 \eta} (D^2_\xi W) \circ (D^2_\xi W) \right) \right] + b_{11} (D^2_\Psi U \circ A_1) - a_{22} U \circ A_2
\]

\[+ d_{11} (D^2_\Psi W) \circ (D^2_\Psi W) \circ A_1 - b_{22} U \circ A_2
\]

\[= d_{22} \psi \circ A_2 - \frac{b_{12}}{2 \eta} (D^2_\Psi W) \circ (D^2_\Psi W) \circ A_1 + \kappa_\alpha \eta \psi \circ (D^2_\Psi W) = 0, \quad \text{(32b)}\]

where \( \circ \) shows the Hadamard product \([59]\) and \( A^T = [1/\xi_1^2, 1/\xi_2^2, \ldots , 1/\xi_N^2] \). Following the same procedure used for the discretization of the equilibrium equation, one can discretize the BCs (Eqs. (18)) similarly. The set of nonlinear equations of the domain can be defined by:

\[
G : \mathbb{R}^{2N+1} \rightarrow \mathbb{R}^{2N},
\]

\[
G(P, X) = 0,
\]

\[
X^T = [U^T, W^T, \Psi^T],
\]

(33)

where parameter \( P \) is the axial load.

The previous equation due to the presence of \( P \) is a parameterized equation. Here, by employing the pseudo-arc length continuation technique, this equation will be solved. To this end, by substituting the residual of equations relevant to boundaries into the residual of the domain \( G(P, X) \), the edge conditions are satisfied. This assumption implies that the elements of
G related to the grid points must be substituted with those of discretized BCs.

3.3. Vibration study in the postbuckled region

Herein, the aim is to examine the linear free vibration of a buckled CNTRC plate. To accomplish this goal, by introducing small disturbances \( u_d, w_d, \) and \( \psi_d \), respectively, around the buckled configurations \( u_s, w_s, \) and \( \psi_s \), the time evolution of that disturbance will be obtained as follows:

\[
\begin{align*}
\dot{u}(\xi, \tau) &= u_s(\xi) + u_d(\xi, \tau), \quad \dot{w}(\xi, \tau) \\
&= w_s(\xi) + w_d(\xi, \tau), \quad \dot{\psi}(\xi, \tau) \\
&= \psi_s(\xi) + \psi_d(\xi, \tau).
\end{align*}
\]  

(34)

Thereafter, by inserting the previous equation into the governing equation and ignoring the nonlinear time-dependent terms, the linear free vibration problem is obtained by:

\[
m\ddot{x} + kx = 0,
\]

(35)

where dot indicates the derivative with respect to \( \tau \), \( x \) denotes the generalized coordinate, and \( m \) and \( k \) are the inertia and stiffness matrices, respectively, which can be determined by:

\[
x^T = [u_d, w_d, \psi_d],
\]

\[
m = \begin{bmatrix}
I_0 & 0 & 0 \\
0 & I_0 & 0 \\
I_1 & 0 & I_2
\end{bmatrix},
\]

\[
k = \begin{bmatrix}
k_{uu} & k_{uw} & k_{uw} \\
k_{uw} & k_{ww} & k_{w\psi} \\
k_{uw} & k_{w\psi} & k_{\psi\psi}
\end{bmatrix}.
\]

(36)

The elements of \( k \) are introduced as follows:

\[
k_{uu} = a_{11} \left( \frac{\partial^2}{\partial \xi^2} + \frac{1}{\xi} \frac{\partial}{\partial \xi} \right) - a_{22} \frac{1}{\xi^2},
\]

\[
k_{uw} = \frac{a_{11}}{\eta} \left[ \frac{\partial w_s}{\partial \xi} \frac{\partial}{\partial \xi} + \frac{\partial w_s}{\partial \xi} \frac{\partial^2}{\partial \xi^2} + \frac{1}{\xi} \frac{\partial w_s}{\partial \xi} \right] \\
- \frac{a_{12}}{\eta} \frac{\partial w_s}{\partial \xi} \frac{\partial}{\partial \xi},
\]

\[
k_{uw} = \frac{1}{\eta} \left( a_{11} \frac{\partial}{\partial \xi} + a_{12} \frac{1}{\xi} \frac{\partial}{\partial \xi} \right) \left( \frac{1}{\xi} \frac{\partial w_s}{\partial \xi} + \frac{\partial^2 w_s}{\partial \xi^2} \right) \\
+ \frac{1}{\eta} \left( a_{11} \frac{\partial^2}{\partial \xi^2} + a_{12} \left( \frac{1}{\xi} \frac{\partial}{\partial \xi} - \frac{1}{\xi^2} \right) \right) \frac{\partial w_s}{\partial \xi},
\]

(37a)

\[
k_{uw} = k_s \alpha_{g5} \left( \frac{\partial^2}{\partial \xi^2} \right) + \frac{1}{\xi} \frac{\partial}{\partial \xi} \left( \frac{1}{\xi} \right),
\]

\[
k_{uw} = k_s \alpha_{g5} \left( \frac{\partial^2}{\partial \xi^2} + \frac{1}{\xi} \frac{\partial}{\partial \xi} \right) - \frac{a_{22}}{\xi^2},
\]

\[
k_{uw} = \frac{b_{11}}{\eta} \left( \frac{\partial w_s}{\partial \xi} \right) \left( \frac{\partial^2}{\partial \xi^2} + \frac{1}{\xi} \frac{\partial}{\partial \xi} \right) \\
- \frac{d_{12}}{\eta} \frac{\partial w_s}{\partial \xi} \frac{\partial}{\partial \xi} - k_s \alpha_{g5} \frac{\partial}{\partial \xi},
\]

(37b)

\[
k_{w\psi} = \frac{d_{22}}{\xi^2} + \frac{b_{11}}{\eta} \left( \frac{\partial^2}{\partial \xi^2} + \frac{1}{\xi} \frac{\partial}{\partial \xi} \right) - k_s \alpha_{g5} \eta \frac{\partial}{\partial \xi}.
\]

(37c)

Now, by employing the GDQ technique, one can discretize Eq. (35) as follows:

\[
\dot{M}\ddot{x} + Kx = 0,
\]

(38)

in which:

\[
x^T = [U_d^T, W_d^T, \Psi_d^T].
\]
\[
M = \begin{bmatrix}
I_0 D^0_\xi & 0 & I_1 D^0_\xi \\
0 & I_0 D^0_\xi & 0 \\
I_1 D^0_\xi & 0 & I_1 D^0_\xi \\
\end{bmatrix},
\]
\[
K = \begin{bmatrix}
K_{uu} & K_{uw} & K_{u\psi} \\
K_{wu} & K_{ww} & K_{w\psi} \\
K_{pu} & K_{pw} & K_{p\psi} \\
\end{bmatrix}.
\]  

(39)

The components of \( K \) are determined by:

\[
k_{uu} = a_{11}(D^2_\xi + A_1 \diamond D^1_\xi) - a_{22}A_2 \diamond D^0_\xi,
\]

\[
k_{uw} = \frac{a_{11}}{\eta} \left[ (D^2_\xi W_s) \diamond (D^1_\xi W_s) + (D^1_\xi W_s) \diamond D^2_\xi
\right]
+ A_1 \circ (D^1_\xi W_s) \diamond D^1_\xi
- \frac{a_{12}}{\eta} \left[ A_1 \circ (D^1_\xi W_s) \diamond D^1_\xi \right],
\]

\[
k_{u\psi} = b_{11}(D^2_\xi + A_1 \diamond D^1_\xi) - b_{22}A_2 \diamond D^0_\xi,
\]

\[
k_{wu} = \frac{1}{\eta} (a_{11} D^1_\xi + a_{12} A_1)
\]
\[
\diamond (A_1 \circ (D^1_\xi W_s) + D^2_\xi W_s)
+ \frac{1}{\eta} \left\{ a_{11} D^2_\xi + a_{12} (A_1 \diamond D^1_\xi - A_2 \diamond D^0_\xi) \right\}
\diamond (D^1_\xi W_s),
\]

\[
k_{wu} = k_d a_{11} (D^2_\xi + A_1 \diamond D^1_\xi)
\]
\[
+ \frac{a_{11}}{\eta^2} \left( (D^2_\xi W_s + A_1 \circ (D^1_\xi W_s)) \circ (D^1_\xi W_s) \right)
\diamond (D^1_\xi + D^2_\xi W_s) + (D^2_\xi W_s) \diamond D^1_\xi
\]
\[
\diamond (D^1_\xi W_s) + \frac{1}{\eta} \left\{ a_{11} \left( D^1_\xi U_s \right) + \frac{1}{2\eta} \left( D^1_\xi W_s \right) \diamond (D^1_\xi W_s) \right\} + a_{12} A_1
\]
\[
\diamond (D^1_\xi U_s) + b_{11} D^1_\xi \Psi_s + b_{12} A_1 \circ (D^1_\xi W_s)
\]
\[
\diamond (D^2_\xi + A_1 \diamond D^1_\xi)
+ \frac{1}{\eta} \left\{ a_{11} \left( D^2_\xi U_s + \frac{1}{\eta} \left( D^2_\xi W_s \right) \circ (D^2_\xi W_s) \right) \right\}
+ a_{12} (A_1 \circ (D^1_\xi U_s) - A_2 \circ (D^2_\xi U_s))
\]
\[
+ b_{11} D^2_\xi \Psi_s + b_{12} \left( A_1 \circ (D^2_\xi W_s \right)
\]
\[
-A_2 \circ (D^1_\xi W_s) \right\}) \diamond D^1_\xi - P \left( D^2_\xi + A_1 \circ D^1_\xi \right),
\]

(40b)

\[
k_{w\psi} = k_d a_{11} (D^2_\xi + A_1) + \frac{1}{\eta} \left\{ b_{11} D^1_\xi + b_{12} A_1 \right\}
\]
\[
\diamond (D^2_\xi W_s + A_1 \circ D^1_\xi)
+ \frac{1}{\eta} \left\{ b_{11} D^2_\xi + b_{12} \left( A_1 \circ D^1_\xi \right)
\diamond (D^1_\xi W_s),
\]

(40a)

\[
k_{\psi u} = b_{11}(D^2_\xi + A_1 \diamond D^1_\xi) - b_{22}A_2 \diamond D^0_\xi,
\]

\[
k_{\psi w} = \frac{b_{11}}{\eta} \left( D^1_\xi W_s \diamond D^2_\xi + D^2_\xi W_s \diamond D^1_\xi + A_1
\]
\[
\diamond (D^1_\xi W_s) \diamond D^1_\xi - \frac{a_{12}}{\eta} A_1 \circ (D^1_\xi W_s)
\diamond (D^1_\xi - k_d a_{11} \eta D^1_\xi),
\]

(40c)

where \( \diamond \) represents the SJT product (SJT is the abbreviation of Shanghai Jiao Tong Univ.) \([59,60]\). By considering the harmonic solution of the form \( \mathbf{X} = \mathbf{X}_e e^{i\omega \tau} \), Eq. (39) turns into:

\[
-\omega^2 \mathbf{M} \mathbf{X} + \mathbf{K} \mathbf{X} = (\mathbf{K} - \omega^2 \mathbf{M}) \mathbf{X} = 0,
\]

where \( \omega \) denotes the non-dimensional frequency.

Substitution of the BCs into \( \mathbf{K} \) and \( \mathbf{M} \) and the rearrangement of the discretized equations and the associated BCs yield the following eigenvalue problem:

\[
\begin{bmatrix}
K_{dd} & K_{db} \\
K_{bd} & K_{bb} \\
\end{bmatrix}
\begin{bmatrix}
\mathbf{X}_d \\
\mathbf{X}_b \\
\end{bmatrix} = \begin{bmatrix}
\omega^2 M_{dd} \mathbf{X}_d \\
0 \\
\end{bmatrix}
\]

(42)

where subscripts \( d \) and \( b \) are the domain and boundary mesh grid points, respectively.

Eq. (42) can be uncoupled through the following expressions:

\[
\begin{bmatrix}
K_{dd} - K_{db} (K_{bb})^{-1} K_{bd} \\
K_{bd} & K_{bb} \\
\end{bmatrix}
\begin{bmatrix}
\mathbf{X}_d \\
\mathbf{X}_b \\
\end{bmatrix} = \omega^2 M_{dd} \mathbf{X}_d
\]

(43)

Now, \( \omega_1 (i = 1, 2, 3, \ldots) \) and their corresponding mode shapes \( \mathbf{X}_1^T = \begin{bmatrix} \mathbf{X}_d^T \mathbf{X}_b^T \end{bmatrix} \) can be achieved by finding a solution to Eq. (43).
4. Numerical results and discussion

The formulation and solution procedure developed in the previous sections are utilized to present the numerical results for the postbuckling behavior and the free vibration of the FG-CNTRC annular plates. Effects of various factors on the static equilibrium postbuckling path and frequencies are shown by conducting a non-dimensional study. Poly methyl methacrylate (PMMA) with \( \nu^m = 0.34, \rho^m = 1150 \text{ kg/m}^3, E^m = 2.5 \text{ GPa} \) [26] and armchair (10,10) SWCNTs with \( \nu^{cnt} = 0.175, G^{cnt} = 1.9445 \text{ TPa}, E^{cnt} = 5.6466 \text{ TPa} \) at room temperature (300 K) [61] are selected as matrix and reinforcements, respectively.

Furthermore, the values of CNT efficiency parameters \( \eta_1, \eta_2, \) and \( \eta_3 \) for three different CNT volume fractions are considered as follows [26]:

\[
V^{cnt}_1 = 0.12: \quad \eta_1 = 0.137, \quad \eta_2 = 1.022, \quad \eta_3 = 0.715,
\]
\[
V^{cnt}_2 = 0.17: \quad \eta_1 = 0.142, \quad \eta_2 = 1.626, \quad \eta_3 = 1.138,
\]
\[
V^{cnt}_3 = 0.28: \quad \eta_1 = 0.141, \quad \eta_2 = 1.585, \quad \eta_3 = 1.109.
\]

In what follows, a sequence of letters including “SS” and “C” is used to represent the simply supported and clamped BCs, respectively.

To provide a convergence study and illustrate the accuracy of mathematical modeling, solution procedure, and numerical results, the natural frequency parameters of isotropic annular plates are provided in Table 1. It can be seen that the results are converged by increasing \( N \) and are in excellent agreement with those of Li et al. [53]. In this study, \( N = 21 \) is used in all computational efforts. In addition, in Table 2, the critical buckling load parameters associated with various inner-to-outter radius ratios are compared with those given in [62], illustrating very well agreement.

Depicted in Figure 2 are the static equilibrium postbuckling paths as the maximum non-dimensional deflection, \( w_{\text{max}} \), versus the non-dimensional compressive radial load (Nom. dim. radial load; \( P = \bar{P}/A_{110} \) where \( \bar{P} \) is the dimensional compressive radial load) for the three different prescribed distributions of CNTs in the CNTRC annular plates corresponding to four various combinations of simply supported and clamped edge supports. According to this figure, it is revealed that for a fixed value of the radial load, the maximum deflection, \( w_{\text{max}} \), corresponding to an FGO-CNTRC annular plate is larger than those of the other two types of CNTRC plates; the FGO-CNTRC annular has the lowest critical buckling load and the highest critical buckling load, and the maximum load-carrying capacity belongs to the FGO distribution pattern. It can be concluded from this figure that the addition of more CNTs to the upper and lower surfaces of FG-CNTRC annular plates results in a considerable increase in the total stiffness of system and induces more resistance against bending. In addition, it is observed that the FG-CNTRC plates with C-C edge conditions have minimum values of maximum deflection and, subsequently, maximum values of critical buckling load, whereas, for the case of the FG-CNTRC annular plates with fully simply supported edges, an opposite trend is seen. The dependence of the non-dimensional frequency (Nom. dim. frequency; \( \omega = 2\pi\sqrt{f_{\text{m}}/A_{110}} \) where \( \omega \) is the natural frequency) upon the non-dimensional compressive radial load in the pre- and post-buckled states is exhibited in Figure 3. Based on the results exhibited in Figure 3, it can be concluded that the fundamental frequencies of FG-CNTRC annular plates in the pre-

Figure 2. Equilibrium post-buckling path of FG-CNTRC annular plates for three different distributions of the CNTs ($b/h = 40, V_{cntr} = 0.17, a/b = 0.2$).

Figure 3. Vibration behavior of pre- and post-buckled FG-CNTRC annular plates for three different distributions of the CNTs ($b/h = 40, V_{cntr} = 0.17, a/b = 0.2$).
buckled state decrease with an increase in the radial load. This is because the stiffness of FG-CNTRC annular plates decreases by increasing the compressive radial load. By increasing the compressive radial load to a new high, the stiffness matrix becomes a zero matrix at a certain point, called the buckling point. In this point, the FG-CNTRC annular plates do not experience any vibration and, consequently, the fundamental frequency is zero. It can be interpreted that the buckling point is a bifurcation point through which the FG-CNTRC annular plate meets its secondary equilibrium state known as the postbuckling region. Prior to the bifurcation point, the frequencies correspond to the pre-buckling configuration, and those after the critical buckling load are concerned with the vibration in the post-buckled state. For a buckled plate, it is seen that by increasing the compressive radial load, the fundamental frequencies increase. This implies that a buckled plate can withstand additional load without failure. In addition, it is deduced that the dimensionless frequency-load curves are continuous, yet not differentiable at the buckling point. According to this figure, it is observed that at a fixed value of radial load, the fundamental frequencies associated with the FGO-CNTRC plates have lower values than CNTRC annular plates with FGX and UD patterns in the pre-buckled region. While, in the postbuckled region, it is seen that the fundamental frequencies corresponding to FGO-CNTRC plates have larger values than the other two cases. It is due to this fact that the deflection in the postbuckled region intensifies the nonlinear stiffness matrices. In addition, it is implied that the effect of deflection is more significant than the CNT distribution pattern. Hence, at a certain point in the postbuckled region, since the deflection of FGO-CNTRC annular plate is more than two other distribution patterns, its frequency is greater than the annular plate with UD and FGX patterns.

Effects of $V_{cr}^{s}$ on the equilibrium postbuckling path and frequency-response curves are plotted in Figures 4 and 5 for the FGX-CNTRC annular plates. From these figures, it is seen that as $V_{cr}^{s}$ increases, the maximum dimensionless deflection decreases and critical buckling load increases. It means that by increasing $V_{cr}^{s}$, the flexibility of the CNTRC annular plate increases, too. This is due to the considerable stiffness of CNTs. As it is expected, by increasing $V_{cr}^{s}$, the frequencies of the CNTRC annular plates with FGX pattern increase in the pre-buckled region, whereas an opposite trend is observed for the postbuckling configuration.

Figures 6 and 7 show the effects of $b/h$ on the maximum dimensionless deflection and frequency of the FGO-CNTRC plates with C-C, SS-SS, C-SS, and SS-C BCs, respectively. It is observed that an increase in $b/h$ leads to increasing and decreasing the maximum

dimensionless deflection and the critical buckling load, respectively. In other words, an increase in $b/h$ results in a decrease in the postbuckling load-carrying capacity of FG annular plates. According to the dimensionless frequency-radial load curves, it is seen that the frequency in the pre-buckled and post-buckled regions respectively decreases and increases as the plate aspect ratio rises.

Finally, the effects of $a/b$ on the equilibrium postbuckling path and vibration characteristics of the FGX-CNTRC annular plates with C-C, SS-SS, C-SS, and SS-C BCs are shown in Figures 8 and 9, respectively. It is deduced that an increase in $a/b$ decreases the maximum dimensionless deflection and increases the critical buckling load. In other words, the larger the difference between the outer and inner radii, the more stable the CNTRC plate. In addition, it is seen that increasing $a/b$ causes the fundamental frequency to increase in the pre-buckled and deep postbuckled regions. In the post-buckled region, depending on the geometry and compressive radial loading (and, consequently, the deflection of plate), the fundamental frequency may decrease or increase.

5. Conclusion

In this study, a numerical methodology was adopted to investigate the postbuckling and free vibration of FG-CNTRC annular plates with different BCs. To this end, the FSDT along with the von Kármán geometric nonlinearity was utilized to formulate the underlying problem. The UD, FGO, and FG distributions of SWCNTs in the composite plates were considered. Upon employing an equivalent continuum model, the material properties of FG-CNTRCs were estimated. Governing equations were attained by Hamilton’s principle and, then, discretized by a GDQ-based method. Prior to examining the vibration behavior of postbuckled CNTRC plates, postbuckling analysis was performed to obtain the buckling load and equilibrium postbuckling path via the pseudo-arc length continuation scheme. Thereafter, the free vibration problem of the postbuckled CNTRC annular plates was solved as a standard linear eigenvalue equation. Effects of various parameters including types of BCs, CNT volume fraction, outer radius-to-thickness ratio, and inner-to-outer radius ratio on the postbuckling path and fundamental frequencies were investigated. Results showed that at a fixed value of the applied radial load, the fundamental frequencies of FGO-CNTRC plates are the smallest in the pre-buckling region and the largest in the postbuckling region among the given cases. In addition, it was observed that by increasing the outer radius-to-thickness aspect ratio, the fundamental frequencies increase in the prebuckling and deep postbuckling regions.
