ABSTRACT

So far, numerous studies have been developed to evaluate the performance of decision-making units (DMUs) through data envelopment analysis (DEA) technique in different places, but most of these studies have measured the performance of DMUs by efficiency criteria. The productivity is considered as a key factor in the success and development of DMUs and its evaluation is more comprehensive than efficiency evaluation. Recently, the productivity has been considered in DEA technique. The productivity in these studies is often evaluated through the productivity indexes. These indexes require at least two time periods and also the two important elements of efficiency and effectiveness in these studies are not significantly evident. There are few studies that measure productivity through efficiency and effectiveness. This few researches also measure the efficiency and effectiveness in two stages separately. So, the purpose of this study is to develop a new approach in the DEA technique in order to measure productivity of DMUs through efficiency and effectiveness simultaneously, in one stage and interdependently. One case study demonstrates application of the proposed approach in the branches of a Bank. Using proposed approach revealed that efficient branches are not necessarily productive, but productive branches are also efficient.

Keywords: Effectiveness, Efficiency, Productivity, DEA, Productivity indexes

1. Introduction

Nowadays, performance assessment of industrial and economical units plays important role in achieving their managerial success and continuous progress [1]. Various criteria have been proposed as performance evaluation criteria of organizations that efficiency, effectiveness and productivity are the most important of these criteria [2]. Because, productivity is a combination of efficiency and effectiveness simultaneously, therefore, its evaluation will be more complete than the evaluation of effectiveness and efficiency separately [3]. The productivity is a subject of interest to many economists and policymakers, and it is crucial for economic growth and survival [4]. Productivity is also considered as an important element for the operations of the organization and its increase
creates a competitive advantage for organization and is a vital issue for management. Making a profit, reducing costs, and growing an organization in the long-term requires improving productivity [5].

The data envelopment analysis (DEA) is one of the main techniques for analyzing the efficiency of organizations and it is considered as a well-known, popular and standard method for measuring the efficiency of manufacturing and service organizations [6, 7, 8]. According to many experts, researchers and users of operations research, the advantages of DEA technique outweigh its disadvantages [9].

Recently, there are studies that evaluate the productivity of decision-making units (DMUs) through the DEA technique. These studies are divided into the following two categories:

I) productivity evaluation through productivity indicators: in this type of evaluation, productivity is measured through indicators such as Malmquist productivity index and Luenberger productivity index. These indicators are methods for analyzing efficiency changes over a period which have been applied in several fields [10, 11]. In other words, these indicators show that the efficiency of a decision-making unit (DMU) has increased, decreased, or remained constant over a period [11]. Far (1994) first proposed the DEA-Malmquist Productivity Index to measure the growth of productivity and technical progress of DMUs [12]. The Malmquist productivity index is an indicator which shows the total factor productivity growth of a DMU, and it can analyzes the changes of the efficiency between two time periods under the multiple inputs and multiple outputs [13]. The Malmquist productivity index is a non-parametric function of evaluating the productivity with the ratio of the distance function and it has a ratio structure, while the Luenberger productivity index has an additive structure [14]. The Malmquist productivity index generally uses Russell measure or enhanced Russell measure of inefficiency, in which multiplication is used, but the Luenberger productivity index uses slack-based measure of efficiency, in which the addition is used [15]. However, these indicators do not show all factors in a system [16]. These indexes also require at least two time periods to evaluate the productivity of DMUs and also the two important elements of efficiency and effectiveness in these studies are not significantly evident.

II) The productivity evaluation through efficiency and effectiveness: As we know, DEA is mostly used to evaluate the efficiency of DMUs [17] and the effectiveness is not considered in it, while effectiveness is as important as efficiency for evaluating DMUs [3].
Many studies have developed organizational effectiveness models, but they have not used a suitable analytical tool to evaluate effectiveness [18]. There exist few researches to measure productivity through efficiency and effectiveness [5] that this few researches also measures efficiency and effectiveness in two stages. Efficiency and effectiveness are complementary and they are not independent of each other but they have a different meaning. [16]. Therefore, they must be measured in one stage, simultaneously and interdependently.

The publications related to DEA can be divided into two groups: The first group uses data envelopment analysis to evaluate the performance of different organizations and the second group develops the original model theoretically [19] that the present study is from the second one. According to the above information, the aim and innovation of the present study is to propose a new approach of the DEA technique that can measure the productivity of DMUs through efficiency and effectiveness in one stage, interdependently and simultaneously. The effectiveness is formulated in DEA technique to achieve this purpose. Using the proposed model, we can easily and in one stage and at the same time, measure the productivity of DMUs through effectiveness and efficiency. This proposed model has all the advantages of the original DEA technique and in addition, can evaluate the effectiveness of DMUs along with efficiency. For a case study in this study, the productivity of Maskan bank branches in Gilan province was evaluated through efficiency and effectiveness, but it can be used in all organizations that have similar inputs and outputs. After measuring the productivity of the branches, it became clear that efficient branches are not necessarily productive, but productive branches are also efficient.

Figure 1 shows main steps of solving the problem.

[Please insert Figure 1 about here]

2. Literature review

In this section, first the keywords of the research will be described and then previous studies related to the research topic will be presented. Finally, the gap between previous studies and the current study will be explained.

1.2. Efficiency, effectiveness and productivity

One of the key purposes of the organization is to improve performance because according to Azar and Zaree [20], leads to increased employee motivation, decision support, improvement in organizational learning, continuous improvement and increased
communication and coordination. Various criteria have been proposed as performance evaluation criteria of organizations that efficiency, effectiveness and productivity are the most important of these criteria [2].

The efficiency is defined in various terms such as increasing output, reducing costs, increasing profits and "doing things right" [21]. This term is also defined as

\[
\text{efficiency} = \frac{\text{actual consumption}}{\text{expected consumption}} = \frac{\text{produced output}}{\text{consumed input}} = \frac{\text{output}}{\text{input}}
\]

[5].

The effectiveness is defined as choosing activities in the right way, being able to achieve predetermined goals and "doing the right thing" [5]. According to Lee and Johnson [16], the effectiveness is determined by the distance between observed outputs and a set of desired goals. Azadi et al. [3] also defined the effectiveness of a DMU as

\[
\text{effectiveness} = \frac{\text{output}}{\text{goal}}
\]

Roghanian et al. [5] define productivity as a combination of efficiency and effectiveness as

\[
\text{productivity} = \frac{\text{output}}{\text{input}} + \frac{\text{output}}{\text{goal}}
\]

Moreover, Asia Productivity Organization (APO) defines the productivity as: “Productivity = Efficiency + Effectiveness = Doing things right + Doing the right things” [5].

According to the information in this section, we find that the sum of efficiency and effectiveness is the productivity and the formula of efficiency and effectiveness can also be extracted from this section. So,

\[
\text{productivity} = \frac{\text{output}}{\text{input}} + \frac{\text{output}}{\text{goal}}
\]

2-2. Relationships between Efficiency, effectiveness and productivity

The efficiency is “doing the things right” according to definition; in the same way, the effectiveness is defined as “doing the right things”, and productivity is referred to the sum of efficiency and effectiveness, and includes both of them. That is, the productivity include measurement and assessment of return and outcome of an organization's activities against the
goals and the spent resources [2]. Many studies have described the relationship between these three concepts in figures, the most important of which are mentioned below.

Azar and Zaree [22], Lee and Johnson [16] and Roghanian et al. [5] drew Figure 2, 3 and 4 respectively. If we pay attention, we find that all three figures are composed of two-dimensional matrices, and only in each one, the titles in the matrix cells are different from each other. In other words, each of these studies looked at the relationship between efficiency and effectiveness from different perspectives. The fourth cell of each matrix indicates the high efficiency and effectiveness (productivity) of an organization, and the other cells indicate that the organization is low in one or both of them (unproductively). In Figure 2, the relationship between efficiency and effectiveness is profit-oriented. The fourth cell of this matrix indicates that high efficiency and effectiveness lead to long-term and sustainable profitability. The rest of the matrix cells are weak in profitability. In Figure 3, the relationship between efficiency and effectiveness is strategic-oriented, meaning that the organization has a specific strategy for each of the matrix cells. The fourth cell of this matrix shows that the organization is a leader in the strategy of developing new markets and innovation due to its high efficiency and effectiveness. In other words, the organization is optimal in choosing its production and sales strategies, which leads to competitive advantage. The organization is weak in terms of production or sales strategies in the rest of the matrix cells. In Figure 4, the relationship mentioned is customer-oriented, meaning that the organization is moving toward customer satisfaction. In the fourth cell of this matrix, the organization with the minimum resources brings the maximum satisfaction to customers. The organization performs poorly in the rest of the matrix cells in terms of customer service or resource consumption.

According to the above information, we can set the relationship between efficiency and effectiveness and productivity as Figure 5 [22].

If we analyze the information presented in this section, we will find that to evaluate productivity through efficiency and effectiveness, it is necessary that efficiency and effectiveness considered interdependently and should be evaluated simultaneously and in one
stage. Also, efficiency and effectiveness are two integral components of productivity and it is better to use these two components to evaluate productivity.

3.2. DEA

Farrell [23] introduced the nonparametric methods for estimating efficiency for the first time. There was an input and an output in his case to measure efficiency. Charles et al. [24] developed the Farrell view, and provided a fractional and nonlinear mathematical programming model to measure efficiency with multiple inputs and outputs. This model was called the DEA model, and the model was named Charnese, Coopere and Rhodes (CCR) model due to the first letter of the developers’ name. Banker et al. [25] presented a new model named Bankere, Charnese and Cooper (BCC) model, with a little change in the CCR model. Accordingly, the DEA is a boundary-based nonparametric evaluation model which is used to measure the relative efficiency and performance of a set of comparable entities, called DMUs and in converting inputs to outputs [26]. The performance of a DMU is calculated by comparing its efficiency with the best observed performance in the data set. This linear programming model determines the optimal weights for inputs and outputs needed to maximize the efficiency [27]. The basic DEA models are faced with two assumptions of Constant Return to Scale (CRS) and Variable Return to Scale (VRS), the CRS assumption is called the CCR model and the VRS assumption is called the BBC model [28]. The CCR model measures the technical efficiency of DMUs [29] and is used when the units operate at their optimal size [28]. The BCC model calculates the pure technical efficiency [29] and is used when the units do not operate under optimal size conditions [28]. Cadavid et al. [29] describes the relationship between technical efficiency (CCR) and pure technical efficiency (BCC) through the following:

\[
\text{Scale efficiency} = \frac{\text{CCR efficiency}}{\text{BCC efficiency}},
\]

\[
\text{CCR efficiency} = \text{BCC efficiency} \times \text{scale efficiency}
\]

In another classification, the CCR and BCC models are called radial models, and the non-radial models include additive model, multiplicative model, range-adjusted measure (RAM), and slack-based measure (SBM) [30].

Advantages of DEA are:
1- It does not need to define the mathematical form of the production function.

2- It is useful to discover relationships that are impossible for other methods.

3- It can handle multiple inputs and outputs.

4- It can be used for any input-output measurement.

5- In this technique, resources that are inefficient in each DMU can be identified and analyzed [31].

6- It avoids the influence of subjective factors on the evaluation results [32].

7- In this method, inputs and outputs can have different units of measurement such as quantitative and qualitative [33].

8- DEA application is easy and interpretable [7].

Clermont and Schaefer [9] state that “from the viewpoint of many researchers and users in the field of Operations Research, the advantages of DEA seem to outweigh the disadvantages”.

According to the information in this section, the reasons for using the DEA technique in this study to evaluate the performance of DMUs is identified and also the concepts described in this section can be used in Section 3.

4.2. Related works

In this section, a number of previous studies on the productivity of DMUs through the DEA are reviewed.

Kao and Tai liu [8] propose a model based on the network DEA (NDEA) approach to measure the overall efficiency of decision-making units in a multi-period system, taking into account the operations in each period. The overall efficiency of 22 commercial banks has been measured through this model and also the Malmquist productivity index technique has been used to measure the efficiency changes between the two periods. Fujii et al. [34] applied a new methodology using the weighted Russell directional distance model to measure technical inefficiency, and Malmquist productivity index-DEA and Luenberger productivity index-DEA models to evaluate productivity growth of the banking industry over the period from “2004 to 2011”. The results show that the levels of inefficiency are significantly
different among the three ownership structures of banks in India. Salarieh et al. [35] using Malmquist productivity index-DEA method investigated the effects of efficiency changes and technology on productivity growth of Iran's agricultural sector in the period 2004-2013. The results show that efficiency changes play a dominant role in productivity growth and the share of technology changes is small. Falavigna et al. [10] applied the two-stage analysis by Simar and Wilson (2007) and the Malmquist productivity index-DEA method in order to better understand the impact of a specific policy on the productivity of the Italian tax judiciary. The results of this study showed that judging is a human-centered activity and although their careful organization is necessary for the efficiency of the courts, the role of judges is still vital. Liang yang et al. [32] surveyed the inefficiency and productivity of 64 Chinese universities from 2010 to 2013 using a general two-stage network directional distance framework with carry-over variable to evaluate the inefficiency of universities and a Luenberger productivity index-DEA model to measure productivity changes over time. The results showed that the Luenberger productivity index of universities has increased significantly over time. Sadeghi et al [36] has evaluated the performance of private banks in Iran with the help of DEA. In this study, using DEA approach, a two-stage model has been designed to measure the efficiency and effectiveness of banks during different time periods. Using this model, the efficiency and effectiveness score of each bank in each time period is obtained. The results show that fully efficient or fully efficient banks in a period are not necessarily the best banks in terms of performance in that period. Fujii et al. [37] in the first stage, evaluated the bank's efficiency and productivity changes in EU28 countries using weighted Russell directional distance and Malmquist productivity index-DEA models, and in the second stage, with a disaggregated approach, analyzed the contribution of individual bank inputs in its efficiency and productivity growth and in the third stage tested the convergence of EU28 Bank productivity with the inefficiency of individual bank inputs. They found no evidence of group convergence for bank productivity but found evidence of convergence in changing bank efficiency and technical change. Aduba and Asgari [4] using DEA and Malmquist productivity index and log-linear learning models, empirically estimated the productivity and technological learning of manufacturing industries. The result shows negative total factor productivity growth between 2000 and 2014. Li et al. [14] used the Malmquist productivity index-DEA model to evaluate China's total factor productivity between 1978 and 2016 under resource and environmental constraints. The results showed that under conditions of resource and environmental constraints, China's total factor productivity is slow in growth. Song et al. [13] used the Malmquist productivity index-DEA
model to evaluate the scientific productivity of China's universities. The results show that due to technological progress, the productivity of Chinese universities has increased significantly between 2009 and 2016.

It can be seen that the above studies measure the productivity of DMUs through productivity indicators such as Malmquist productivity index and Luenberger productivity index, or that they evaluate the productivity of decision-making units through efficiency and effectiveness in two stages. For the reasons presented in Section 2.2, those studies that measure productivity through efficiency and effectiveness have more advantages than studies that measure productivity through productivity indicators. In addition, studies based on productivity indicators requires at least two time periods. Studies that measures productivity through efficiency and effectiveness is also two-stages. Therefore, as mentioned in the introduction, we are looking for an approach that measures the productivity of decision units through efficiency and effectiveness in one stage, in a period, simultaneously and interdependently.

3. Proposed approach

Based on Section 3-2, the CCR model presented by Charles et al [24] is in relation (1):

$$\begin{align*}
\text{Max } E_k &= \sum_{r=1}^{s} u_r Y_{r0} \\
\text{s.t. } \sum_{r=1}^{m} v_i X_{i0} &\leq 1, \quad j = 1, 2, \ldots, n \\
\sum_{i=1}^{m} v_i X_{ij} &\geq \varepsilon, \quad r = 1, 2, \ldots, s; \quad i = 1, 2, \ldots, m
\end{align*}$$

Consider n DMUs (j= 1,2,…,n) under assessment. Each DMU consumes m inputs (i=1,2,…,m) and produces s outputs (r=1,2,…,s) denoted by \( X_{1j}, X_{2j}, \ldots, X_{mj} \) and \( Y_{1j}, Y_{2j}, \ldots, Y_{sj} \) respectively. The objective function \( E_k \) is maximized for every DMU individually, where \( X_{ik} \) and \( Y_{rk} \) are the ith input and rth output of DMU0; \( u_r \) and \( v_i \) are the weights of the outputs and inputs, respectively and \( \varepsilon \) is a small non-archimedean number for restricting the DMU to assign 0 weight to unfavorable factors [38].
However, relation (1) only measures the efficiency of DMUs. In order to be able to measure the productivity of DMUs through efficiency and effectiveness, it is necessary to formulate effectiveness in relation (1). As discussed in Section 1-2, we can define effectiveness as follows:

\[
\text{effectiveness} = \frac{\text{outputs}}{\text{goals}}.
\]

We define the effectiveness of a DMU as the ratio of the output to the predetermined goal as follows:

\[
\text{effectiveness of } DMU_0 = \frac{\text{weighted outputs of } DMU_0}{\text{weighted standard outputs (goals) of } DMU_0} = \frac{\sum_{r=1}^{rk} u_r Y_{r0}}{\sum_{r=1}^{rk} \eta_r g_{r0}} \quad \text{Relation (2)}
\]

Where, equation \( \eta_r g_{r0} \) is weighted standard outputs (goals) of DMU\(_0\).

As discussed in Sections 1-2 and 2-2, productivity is the sum of efficiency and effectiveness; then the Relation (2) is incorporated in the Relation (3) as follows:

\[
\text{Max } p_0 = \sum_{r=1}^{rk} \frac{u_r Y_{r0}}{mk} + \sum_{r=1}^{rk} \frac{u_r Y_{r0}}{\eta_r g_{r0}} \quad \text{Relation (3)}
\]

\[
\sum_{r=1}^{rk} \frac{u_r Y_{rj}}{mk} \leq 1, \quad j = 1, 2, \ldots, n
\]

\[
\sum_{i=1}^{i} v_{i} x_{i} \leq 1, \quad i = 1, j
\]

\[
\sum_{r=1}^{rk} \frac{u_r Y_{rj}}{rk} \leq 1, \quad j = 1, 2, \ldots, n
\]

\[
\sum_{r=1}^{rk} \eta_r g_{rj} \leq 1
\]

\[
u_r, v_i, \eta_r \geq \epsilon, \quad r = 1, 2, \ldots, rk; \quad i = 1, 2, \ldots, mk
\]

Relation (3) is nonlinear and can be linearized. To ensure the solvability, two extra constraints are added for DMU\(_0\) to transform the fractional DEA model into a linear programming model [39]. The proposed model can then be solved by LINGO software.
So, we have:

$$\text{MAX } P_0 = \sum_{r=1}^{r_k} u_r Y_{r0} + \sum_{r=1}^{r_k} U_r Y_{r0}$$

Relation (4)

s.t.

$$\sum_{i=1}^{v_i} x_{ij0} = 1$$

$$\sum_{r=1}^{\eta_r} f_{r0} = 1$$

$$\sum_{r=1}^{\eta_r} g_{rj} \leq 0, \quad j = 1, 2, \ldots, n$$

$$\sum_{r=1}^{U_r} Y_{rj} - \sum_{i=1}^{v_i} x_{ij} \leq 0, \quad j = 1, 2, \ldots, n$$

$$u_r, v_i, \eta_r \geq \varepsilon, \quad r = 1, 2, \ldots, r_k; \quad i = 1, 2, \ldots, mk$$

As the contribution of this study the Relation (4) says if $p_0$ is equal to 2, then the DMU is productive and if it is less than 2, it is non-productive. The DMU may be efficient but not productive but if the DMU is productive, it will certainly be efficient. Using relation (4), we can to measure productivity of DMUs through effectiveness and efficiency easily, in one stage, in a period, simultaneously and interdependently. Therefore, the purpose of the research will be met through relation (4).

4. Case study

This section presents the experimental study on the branches of bank. The banking plays the role of mediator between the net savers and net borrowers. Banks deal with people's most liquid asset, and run country's economy [31]. The efficiency and quality of services provided by banks not only have a significant impact on economic growth but also play a very important role in the daily life of each individual [40]. Therefore, analyzing the performance of banking industry and identifying techniques for evaluating it has become the focus of managers, policymakers, economists, institutions and academic research [7, 41].

Examining the literature on evaluating the performance of the banking industry, we find that there are several methods for this purpose, such as financial ratio analysis, regression analysis, and frontier efficiency analysis [42]. The financial ratios analysis of such as return on assets, loans to assets, loans per employee, deposits per employee and cost to income [43] and the regression analysis, although have a significant impact in many areas of business but
they have limitations that make it unsuitable for evaluating the performance of bank branches. Some limitations of these methods are: failure to use multiple inputs and outputs in each evaluation, the need for a special function to identify different aspects of bank branch operations and the inability to consider all variables [42, 44] (for further information on the limitations of these methods, see references 42, 43, and 44). The frontier efficiency method evaluates the performance of the branch in comparison with the best branch in terms of performance. One of the methodologies for this method can be DEA [42]. Referring to the advantages of the DEA technique in Section 3-2, it can be stated that this technique does not have the limitations of the previous two methods. Also, this method has been used successfully to evaluate the performance of banks and numerous studies have been conducted on measuring the performance of banks by this method [44, 45]. Another reason to use DEA in evaluating the performance of banks is that it able to adapt with small sample sizes and application of categorical variables that are commonly used in country-specific panels of data and this advantage is especially important for banking datasets that are small in nature [7, 46].

The choice of inputs and outputs is perhaps the most important task in employing DEA to measure the efficiency and productivity of DMUs [47]. Banks are considered financial institutions that transform labors, fixed assets, non-operational expenses and operational expenses into deposits, interest income and non-interest income. Fixed assets include materials, space and equipment in this approach. Non-operational expenses include personnel expenses, general and administrative expenses, awards and promotions. Operational expenses include interest expenses. Interest incomes are part of the bank’s income, which is derived from contributions from individuals. Non-interest incomes are another category of bank incomes earned through service fees and financial and investment advisories. These incomes include credit card services, bank guarantee services, electronic banking services, exchange services, letter of credits service, maintenance fees for clients’ documents and securities, and issuing various types of checks. The performance process in the banking industry has been shown in Figure 6 [48].

[Please insert Figure 6 about here]

The research data, related to Maskan Bank Branches by Zarei Mahmoudabadi [48], are provided in Table 1. The data were non-scaled using the norm $n_{ij} = \frac{a_{ij}}{\sum a_{ij}}$ [49]. The
columns related to the goals show the goals for each output that they are earned through interviews and surveys from bank managers. In other words, these columns indicate the standard output (goal) against the actual output to evaluate effectiveness.

[Please insert Table 1 about here]

1.4. The results of bank branches efficiency evaluation using DEA model (Relation 1):

Relation (1) has been used in this section to evaluate the efficiency of bank branches. Using lingo software, the results of this evaluation provided in Table 2.

The DMUs 1, 2, 3, 4, 6, 8, 10, 11, 12, 13, 14, 15, 16 are known as efficient DMUs according to the results presented in Table 2.

[Please insert Table 2 about here]

2.4. The results of bank branches productivity evaluation using proposed model (Relation 4):

The productivity of the bank branches is evaluated by Relation (4) in this section. Using lingo software, the evaluation results are provided in Table 3.

[Please insert Table 3 about here]

It can be observed that the DMUs 1, 2, 4, 6, 8, 10, 12, 13, 14, 16 are productive units in Table 3. Considering figure 7 we find that units 3, 11 and 15 are efficient but not productive. Also the ranking of some units in efficiency and productivity are not the same.

[Please insert Figure 7 about here]

Accordingly, the purpose of this study is to propose a DEA model in order to measuring the productivity of DMUs through efficiency and effectiveness easily, in one stage, in a period of time, simultaneously and interdependently that was met in this section.

5. Conclusions and suggestions

As mentioned in the previous sections, we found that nowadays, performance assessment of industrial and economical units plays important role in achieving their managerial success and continuous progress. The productivity is enumerated as significant
factor in analyzing, monitoring, and supervising the performance that there is a consensus among scholars that the productivity management is important component in continuous improvement and successful management.

In the literature, there were several methods used to measure productivity of DMUs that one of these methods was DEA technique. As mentioned in the previous sections, the DEA technique has many advantages, and for these reasons we chose this technique to evaluate productivity. After reviewing the literature on evaluating the productivity of DMUs through DEA, we found that a few studies have been done on this subject and they were divided into two categories:

1. Evaluating the productivity of DMUs through productivity indicators.

2. Evaluating the productivity of DMUs through efficiency and effectiveness

Then we found that the studies related to the first case require at least two time periods to evaluate the productivity of DMUs and also the two important elements of efficiency and effectiveness in these studies are not significantly evident. Studies related to the second case were very little and they also measured the efficiency and effectiveness of DMUs in two separate stages, while these two elements should be evaluated independently and in one stage. Therefore, a new DEA approach was proposed in this study to evaluate the productivity of DMUs through efficiency and effectiveness. This approach can measure the productivity of DMUs through efficiency and effectiveness simply, simultaneously, and in one stage, and also in this approach, efficiency and effectiveness are evaluated interdependently.

A case study was presented to analyze this approach that the results of this case study can be listed as follows: The branches 1, 2, 3, 4, 6, 8, 10, 11, 12, 13, 14, 15, 16 are known as efficient branches according to the results presented in Table 2 using Relation (1). The branches 1, 2, 4, 6, 8, 10, 12, 13, 14, 16 are productive units in Table 3 using Relation (4). Considering chart 4 we find that branches 3, 11 and 15 are efficient but not productive but any branch which is productive is also efficient. In other words, it is possible that the most efficient branch is not necessarily the most productive branch, and this is because of the effectiveness formula that is included in the calculations. Therefore, the present study with a new approach in DEA technique can measure the productivity of all organizations that have similar inputs and outputs in a simple and understandable way.
Some suggestions for future research, based on the results of this research include:

- Considering that the proposed approach in this study is based on the CCR approach, it can also be implemented using the BCC approach.

- The model parameters are all quantitative and precise, which can be considered as qualitative and imprecise in case of using fuzzy approach.

- The proposed approach can be used in network DEA models.
