

# *Analyzing the Impacts of Gasoline Price Change on Nationwide Trip Demand and Drivers' Behavior Using Regression Discontinuity Design*

Sepehr Saeidi, Zahra Amini\*

*Civil Engineering Department, Sharif University of Technology, Tehran, Iran*

## **Highlights**

- Analyzing a scenario of an abrupt and substantial surge in gasoline price.
- Investigating a nationwide (rather than city or route-specific) case study.
- Exploring the impact of an increase in gasoline price on demand, speed distribution, and traffic violations.

## **Abstract**

Gasoline is one of the essential commodities in today's societies and its price can affect different aspects of citizens' lives. This article studies the impacts of the sudden increase in gasoline price on the volume of intercity traffic at national and provincial scales, along with the changes in driving speed distribution and the percentage of speeding violations. The studied period includes four months in two consecutive years. Data was collected from more than 2400 loop detectors placed on the roads of 31 provinces of Iran. This data is used for implementing Regression Discontinuity Design (RDD) on traffic volume and speeding violation percentage. Statistical measures of speed distribution are also used to examine changes in driving speed. According to the literature, the optimal driving speed for fuel consumption is about 50 to 70 km/h. This study showed a 7.4% increase in the probability of driving in the 50 to 70 km/h range after the price increase. Also, according to research results, the volume of intercity traffic and the percentage of speeding violations has decreased due to the rise in gasoline price.

## **Keywords**

- Gasoline price change,
- Regression Discontinuity Design,
- Traffic volume,
- Speeding violation percentage,
- Driving speed

## 38 **1. Introduction**

39 Gasoline is one of the essential commodities in today's societies. Therefore, the price of gasoline can  
40 affect different aspects of citizens' lives. So far, various studies have been conducted on the effects of  
41 changing gasoline price on public health [1–3], the automotive industry and car dealership [4,5], and  
42 people's daily routines [6]. In addition, gasoline price change affects the demand for different modes of  
43 transportation, such as trains and buses [7,8] and bicycles [9]. The present article examines how gasoline  
44 price would impact private vehicles' driving speed and traffic volume.

45 In Iran, unlike many other countries, the government is responsible for setting a fixed price for gasoline,  
46 which is constant all over the country. As a result, the government changes gasoline prices every several  
47 years for various reasons, such as fiscal crises [10]. In recent years, these changes have always been  
48 aimed at increasing the price of gasoline. During the latest price change, which went into effect on  
49 November 16, 2019, the National Iranian Oil Products Distribution Company (NIOPDC) increased  
50 gasoline price by 50% for private cars using their 60 liters/month quota, and 200% for their over-quota  
51 consumption [10]. This was while CNG<sup>1</sup> and diesel prices were kept unchanged.

52 Since most vehicles in Iran use gasoline as fuel, the increase in gasoline price has significantly affected  
53 different aspects of travel demand. Some of these aspects that receive impact from the change in gasoline  
54 price are the number of trips, length of trips, and driver behavior. The vehicle count recorded by loop  
55 detectors can be an indicator for measuring changes in the count and length of trips (as the trip length  
56 grows, more loop detectors cover the trip). On the other hand, aspects of driver behavior are expected to  
57 change due to the change in the gasoline price are driving speed and the number of speeding violations. In  
58 this study, changes in driving speed and, as a result, the percentage of speeding violations are used to  
59 examine changes in driver behavior. The type and duration of travel in different regions of the country  
60 vary according to the occupations of the drivers, geographical locations, and economic class. Such  
61 demographic factors control the effects of gasoline price change in different regions of the country.  
62 Therefore, this study is conducted at the national and provincial levels to capture the effects of these  
63 demographic factors.

64 According to the statistical yearbook of the Roads and Transportation Organization of Iran, in 2013-2014,  
65 429 million passengers made intercity trips using a class 1 vehicle (cars and vans) for various trip  
66 purposes, such as leisure and work [11]. Many ways can be used to collect these traffic data, such as  
67 pneumatic road tubes, magnetic loops, and piezoelectric sensors [12]. The investigated intercity trip data  
68 is collected by loop detectors installed on Iran's road network. Daily traffic, mean speed, and speeding  
69 violation count data collected from more than 2400 loop detectors in 31 provinces of the country for the  
70 same periods of 4 months in two consecutive years have been examined. Gathered speed data has an  
71 hourly resolution, but traffic data and the number of speeding violations were recorded daily. Since the  
72 data used in this study are collected using loop detectors, in some cases, the data was not recorded, or the  
73 recorded data had an error. The errors in the data could result from inadequate device installation,  
74 inadequate loop sealants, and disconnection of the device wire [13]. Therefore, a correction method in the  
75 case study section was used to resolve these errors in order to prepare the data for doing the regression  
76 discontinuity analysis.

77 The rest of the paper is organized as follows: The next section entails a comprehensive literature review.  
78 Second, the methodology section will explain RDD and its features. Then, the case study, data source,

---

<sup>1</sup> Compressed Natural Gas

79 data processing, and implementation of RDD on data and its results are presented in the case study  
80 section. Finally, the conclusion is provided in the final section.

## 81 **2. Literature Review**

82 Prior to this study, several pieces of research were done on the policies that lead to travel behavior change  
83 [14] and the impacts gasoline price has on transportation demand. While gasoline pricing differs from  
84 road pricing as a travel demand management (TDM) tool, it can still influence the travel behavior of  
85 commuters by increasing the cost of car ownership and diverting some of its demand to public  
86 transportation. However, in places where gasoline prices are obscured by external interventions, it may  
87 not effectively serve as a TDM option. Additionally, social and political reasons may limit its viability as  
88 a TDM option in certain regions, such as Iran. Studies of the effects of rising gasoline price on public  
89 transportation demand in the United States [15,16], Taiwan [17], Australia [18], and Malaysia [19] have  
90 shown that with increasing gasoline price, public transportation demand in short-term, long-term, or both  
91 have grown. Several studies have also examined the effects of changes in gasoline price on the volume of  
92 intracity traffic in Flanders-Belgium [20], Indonesia [21], and Klang Valley-Malaysia [19], in which the  
93 traffic volume has decreased with an increase in gasoline price. Also, following an increase in fuel taxes  
94 in Greece, a similar study was conducted to examine the traffic volume in a single corridor [22].

95 Another factor that is affected by the price of gasoline is driving speed [23], even though some research  
96 shows that the impact of gasoline price change on driving speed is not significant [24]. In general, four  
97 main factors affect fuel consumption: acceleration, speed, slope, and payload [25]. Studies in this field  
98 show that although the optimum speed is different for each car, fuel consumption at speeds of 50 to 70  
99 km/h will be optimal [26]. Also, The U.S. Department of Energy has announced 80 km/h as the highest  
100 fuel-efficient speed [27]. For example, a study by the Federal Highway Administration found that  
101 reducing speed from 112 to 104 km/h would reduce gasoline consumption by about 8.2% [28].  
102 Considering the effect of speed on gasoline consumption, the behavioral changes of drivers due to the  
103 increase in gasoline price are reasonable and shall be examined.

104 Identifying contributory factors in traffic crashes can be somewhat subjective. Some surveys suggest that  
105 one-third of collisions resulting in a fatality involve an element of excessive speed. Moreover, speed is an  
106 aggravating factor in all crashes [29]. In 2002, 31% of all fatalities and 17% of all severe injuries in New  
107 Zealand were due to speeding, based on police judgments [30]. Therefore, studying car speed distribution  
108 can provide helpful information about the changes in car accidents. This study uses driving speed and the  
109 ratio of speeding violations to the total traffic volume (speeding violation percentage) to describe  
110 alterations in drivers' behaviors. Statistical measures of driving speed have been used to study changes in  
111 driving speed.

112 The regression Discontinuity Design method (RDD) is a quasi-experimental evaluation method [31] that  
113 measures the effects of a treatment or an intervention based on the difference between results before and  
114 after the intervention. This method was performed in psychology for the first time. It was used to measure  
115 the effect of a treatment on a random group of students with different abilities [32]. After that, RDD has  
116 been widely used in various fields such as psychology, statistics, and economics [33]. In transportation,  
117 RDD has been used to estimate the impact of road pricing on traffic composition in Milan, Italy [34].  
118 Also, the impact of Ride-Hailing on public transport usage in the United States has been investigated  
119 using RDD [35]. In this paper, RDD is used to measure the impact of the increase in gasoline price on  
120 traffic volume and speed violation percentage.

121 The present research has some main advantages over previous studies. The first advantage is studying a  
 122 case with a sudden and significant increase in gasoline price. It shall be noted that the four main  
 123 components that affect gasoline price are the cost of crude oil, refining costs and profits, distribution and  
 124 marketing costs, and profits and taxes [36]. The most critical factor in the price of gasoline is the price of  
 125 crude oil [37]. Due to the oil crisis of 1973, the oil price was liberalized to fluctuate in line with supply  
 126 and demand [38]. Hence, in all the studied countries, unlike Iran, gasoline price has constantly changed  
 127 over time. The second advantage is the scale of the data examined. In previous studies, public transport  
 128 demand or traffic volume of a particular city or even a specific route was studied. In this study, all car/van  
 129 trips of the whole country are examined. The third, and most important advantage of this paper over  
 130 previous studies is in examining the effect of gasoline price changes on the speed distribution and  
 131 speeding violation percentage. These are not noticed in any of the earlier studies. Also, to measure the  
 132 driving speed variation due to the gasoline price jump, the speed's mean, and variance changes are  
 133 examined before and after the increase in the gasoline price.

### 134 **3. Methodology**

135 The label "RDD" actually refers to a set of design variations. The RDD is a pretest-posttest program-  
 136 comparison group strategy in its most straightforward, traditional form. What makes RDD different from  
 137 other pre-post group designs is the method by which research participants are assigned to conditions [39].

138 RDD can be characterized in two main ways:

- 139 1. Global strategy (Discontinuity at a cut-point): It focuses on a jump in a specific cutoff point.  
 140 Magnitude and sign of the jump are the measuring tools for evaluating treatment impacts [40].
- 141 2. Local strategy (Local randomization): It is based on the premise that differences between  
 142 candidates who miss and make a threshold are random [41].

143 In addition, RDD is being implemented in two main ways:

- 144 1. The Sharp design: All subjects receive their assigned treatment or control condition, so the  
 145 probability of treatment is equal to 1.
- 146 2. The Fuzzy design: Some subjects do not receive their assigned treatment or control condition, so  
 147 the probability of treatment is not equal to 1 [42].

148 A basic model for executing RDD can be seen in Equation 1. This equation measures the expected value  
 149 of the post-treatment measurement based on a rating variable ( $\tilde{x}_i$ ) and a post-treatment measure value  
 150 [43].

151 *Equation 1*

$$152 \quad E(y_i) = \beta_0 + \beta_1 z_i + \beta_2 \tilde{x}_i + \beta_3 \tilde{x}_i z_i + \dots + \beta_{n-1} \tilde{x}_i^n + \beta_n \tilde{x}_i^n z_i$$

153 Where:

154  $\tilde{x}_i = \text{pretreatment measure for individual } i \text{ minus the cutoff value (i.e., } \tilde{x}_i = x_i - x_0 \text{);}$

155  $y_i = \text{posttreatment measure for individual } i;$

156  $z_i = \text{assignment variable} = \begin{cases} 1 & \text{Observation } i \text{ is assigned to the treatment group} \\ 0 & \text{Otherwise} \end{cases}$

157  $s =$  the degree of the polynomial for the associated  $\tilde{x}_i$ ;  
158  $\beta_0 =$  parameter for comparison group intercept at cutoff  $x_0$ ;  
159  $\beta_1 =$  treatment effect parameter;  
160  $\beta_2 =$  linear slope parameter;  
161  $\beta_3 =$  linear interaction parameter;  
162  $\beta_{n-1} =$  parameter for the  $s^{\text{th}}$  order polynomial;  
163  $\beta_n =$  parameter for the  $s^{\text{th}}$  order polynomial interaction term.

164 The above model tries to measure the main effects at the intervention point, which are shown as  $\beta$   
165 coefficients.  $\beta_1$ , which represents the fracture at the cutoff point, is the most crucial measure to be  
166 considered. RDD has excellent potential for evaluating program-based research. Methodologically, the  
167 results of RDD are comparable to the randomized experiments in terms of internal validity. Therefore,  
168 RDD can compete with randomized designs when causal hypotheses are examined [39]. RDD evaluates  
169 the mean effects of an intervention on a subset of society with the fewest assumptions. One of the  
170 advantages of this method is its simplicity. For instance, it only requires a few details on the model  
171 specifications, such as variables that should be included in the model and their functional forms [31]. On  
172 the other hand, one of the limitations of RDD is its functional scope. RDD examines the effects of  
173 treatment for the cut-point locally, where the probability of receiving treatment changes [31]. Since the  
174 estimated effects of the treatment are limited to the site of rupture, the external validity of this method  
175 cannot be considered very desirable. However, in order to obtain internally valid impact estimates, RDD  
176 is recognized as the most rigorous non-experimental approach [44] and is widely used in non-  
177 experimental methods for causal inference and program evaluation [45].

## 178 4. Case study

179 Unlike many countries, gasoline price is the same in all regions of Iran and do not fluctuate with time  
180 until the government sets a new fee. In the last change, on November 19, 2019, the price of gasoline in  
181 Iran increased by 50% after almost four years. In this study, the loop detector's daily data are utilized to  
182 investigate the effects of the gasoline price hike in Iran on the volume of traffic and speeding violation  
183 percentage. The distribution of loop detectors on roads across the country can be seen in Figure 1. The  
184 circle's color indicates the density of loop detectors in each area, and the numbers inside the circles  
185 indicate the number of loop detectors in that area. Orange, green, and blue colors correspond to loop  
186 detectors' high, moderate, and low densities.

187 Each detector can relegate passing vehicles into five different classes:  
188 Class 1: passenger cars and vans;  
189 Class 2: vans, small trucks, and minibusses;  
190 Class 3: ordinary trucks less than 10 meters in length and three axles;  
191 Class 4: buses;  
192 Class 5: trailers and porters with more than three axles.

193 To start the analysis, at the first step, class 1 vehicles were filtered to be used. In the initial data analysis,  
194 less than 5 percent of the data were detected as errors. These errors can be divided into two general  
195 categories: First, no data was recorded for a specific day or period; Second, a significant difference was  
196 observed between the data variations on the same days in two consecutive years. The data was adequately  
197 estimated by applying the historical background in order to resolve these errors.

198 Based on previous studies, people tend to travel more during holidays and weekends than on workdays  
199 [46]. Also, according to real-life experiences, most people start their trip the day before the holiday starts  
200 and return one day after the holiday finishes to take advantage of their vacation as much as possible. In  
201 the present research, weeks are divided into two parts to achieve more accurate results:  
202 holidays/weekends and workdays. For better realization, traffic data are normalized using equation  
203  $y_{normalized_i} = (y_i - y_{min}) / (y_{max} - y_{min})$ . In this equation,  $y_i$  and  $y_{normalized_i}$  represent the original, and the  
204 normalized value of traffic volume/speeding violations count per day. Also,  $y_{min}$  and  $y_{max}$ , respectively,  
205 are the minimum and maximum values in the studied four-month period.

206 The rating variable is a continuous variable that is measured before treatment, determining whether or not  
207 a group or individual is assigned to the treatment. To start establishing RDD analysis, time which is  
208 considered the rating variable, must be transferred to the origin of the coordinates. This sets the intercept  
209 equal to the cutoff. In RDD analysis, when the rating variable is time, the intervention time is considered  
210 the cutoff point [31]. So, the gasoline price change date is considered the intervention point in this case.  
211 The data belong to 120 days, from 23<sup>rd</sup> September to 20<sup>th</sup> January, for two consecutive years (September  
212 2018 to January 2019 and September 2019 to January 2020). Each day is considered an RDD bin for  
213 implementing the models. The intervention occurred on 16<sup>th</sup> November 2019. For convenience, numbers  
214 1 to 120 are assigned to the studying days in order. Thus, number 55 corresponds to the intervention day,  
215  $x_0$ . In order to centralize time and be used as the rating variable for the model, the intervention time is  
216 subtracted from all times ( $\tilde{x}_i = x_i - x_0$ ).

217 The change in the price of gasoline was done without any prior notice. Hence, a psychological shock hits  
218 the country. Since people needed time to adjust to the new conditions, the workdays of the first week after  
219 the intervention were excluded from the analysis. As a result, the duration of the post-test part was  
220 considered longer than the pretest part to neutralize the shock effect.

221 Three fundamental assumptions are needed to implement the RDD model [47]:

- 222 1. Data are derived from a single group. This means no factor can be considered as an intervention  
223 other than treatment. Here, although the data are from 31 provinces and two seasons, the change  
224 in gasoline price is the dominant factor for results. This assumption is discussed later in this  
225 section.
- 226 2. All used data received the same treatment.
- 227 3. There is only one intervention in the studied period.

228 Since the data was available in this case, it was decided to follow the parametric RDD strategy to  
229 establish the model. Considering that the parametric/global approach uses all available data to estimate  
230 treatment effects, it can offer greater precision. But also, it shall be noticed that over such a broad range of  
231 data, it can be challenging to specify the functional form of the relationship between the conditional mean  
232 of the outcome and the rating variable. As a result, there is an augmented risk of bias [42]. Six models  
233 (from linear to cubic) were fitted to the data set to find the most appropriate model.

234 The main challenge of the RDD implementation is choosing the model which describes data behaviors in  
235 the best way. There are two main performance measures to test the models [42]:

- 236 A. F-Test Approach: This method checks whether the selected model is able to accurately measure  
237 the relationships between data. A P-value corresponding to the F-statistic value is also obtained,  
238 which displays the significance of the test. F-Statistic value can be calculated using Equation 2,  
239 where  $n$  is the number of observations,  $k$  is the model's bin indicators count, and  $R^2$  is the

240 regression's R-squared value. Also, subscripts r and u correspond to two different models which  
 241 are being compared.

242 *Equation 2*

$$243 \quad F_{\text{statistic}} = \frac{\frac{R_u^2 - R_r^2}{k}}{\frac{1 - R_u^2}{n - k - 1}}$$

244 B. Akaike Information Criterion (AIC) Approach: AIC is also a measure of the accuracy of a  
 245 function fitted to data relative to another function. It should be noted that this method alone is not  
 246 a measure of the goodness of a model and is used only for analogy. Any model with a lower AIC  
 247 will better describe the data. AIC value can be calculated using Equation 3, where  $\sigma_b^2$  is the  
 248 estimated residual variance based on a model with p parameters (order of the polynomial plus one  
 249 for the intercept).

250 *Equation 3*

$$251 \quad AIC = N \ln(\sigma_b^2) + 2p$$

252 All RDD models are implemented using the *statsmodels* package [48] in Python. Traffic volume data  
 253 from all the detectors for the mentioned time interval, including weekdays, weekends, and holidays were  
 254 used for model implementation. The results of the above tests for the six mentioned models are given in  
 255 Table 1 and Table 2. The RDD method is inherently a dual fit on the test data. Therefore, the value of R-  
 256 squared, an evaluation method for fitting accuracy, is also reported in these tables. As can be seen in  
 257 Table 1 and Table 2, there is no significant difference between the models' R-squared values. On the other  
 258 hand, the F-statistic value for all models is statistically significant, so the data from each bin adds  
 259 additional information to the model. This indicates that the tested model is over-smoothing the data.  
 260 Nevertheless, due to the short time intervals in the data, the temporal nature of the data, and the absence  
 261 of significant differences between the different models' P-values, the linear model in Equation 4 is the  
 262 most optimal choice.

263 *Equation 4*

$$264 \quad y_i = \beta_0 + \beta_1 z_i + \beta_2 \tilde{x}_i + \varepsilon_i$$

265 Where:

266  $\tilde{x}_i$  = *The rating variable for observation i, centered at the cut – point;*

267  $y_i$  = *Posttreatment measure for individual i;*

268  $z_i$  = *Assignment variable* =  $\begin{cases} 1 & \text{Observation } i \text{ is assigned to the treatment group} \\ 0 & \text{Otherwise} \end{cases}$

269  $\beta_0$  = *Intercept;*

270  $\beta_1$  = *Represents the marginal impact of the change at the cut – point;*

271  $\beta_2$  = *Line slope;*

272 This study was performed in two separate groups on the data of workdays and weekends/holidays (in the  
273 rest of the article, referred to as holidays). To examine each group, a separate linear RDD model was  
274 implemented. The validity test results of these models are given in Table 3 and Table 4.

275 As mentioned in the first hypothesis of the RDD method, the basic premise in implementing the RDD is  
276 that the change in gasoline price has been the only practical factor. This study is performed for the same  
277 period of two consecutive years to validate this hypothesis. As shown in Figure 2 and Figure 3, no sharp  
278 change in either chart of the previous year's data can't be seen. So, it can be concluded that any change in  
279 the studied parameters is only due to changes in the gasoline price, and other factors have no significant  
280 impacts.

281 In Figure 2 and Figure 3, 2019-2020 data are represented with purple circles, while red circles show the  
282 comparison cases in 2018-2019. Also, the green points in Figure 2 represent the shock effect which is not  
283 included in the analysis. The cutoff value in this example occurs on the 55<sup>th</sup> day, which is corresponded to  
284 zero and is indicated by the green vertical line. All data for days before 0 are recorded while the gasoline  
285 price has not been changed; the remainder (i.e., those to the right of the cutoff) are assigned to days on  
286 which the price was increased. The solid lines represent the linear regression of the pretest and post-test  
287 for each year. In the absence of a treatment effect, the critical assumption is that the regression line would  
288 continue to the other side of the cutoff line (i.e., like the 2018-2019 RDD estimation).

289 The effect of changing gasoline price on the volume of intercity traffic is studied for the whole country  
290 and each province separately. Also, the effects of gasoline price variation on changing drivers' behavior  
291 have been investigated from two aspects, driving speed, and the number of speeding violations.

#### 292 **4.1. Nationwide Traffic Volume Changes Results**

293 As mentioned in the previous sections, this study is conducted in two separate sections for workdays and  
294 holidays. The primary measure of the impact is the jump magnitude in the chart or the  $\beta_1$  coefficient in  
295 Equation 4. RDD model outputs confirm the previous claim about the discontinuity in the graph. As is  
296 evident in Figure 2 and Figure 3, there are no jumps in the chart during 2018-2019, but a significant  
297 change in the traffic volume can be seen as the result of the gasoline price change. The  $\beta_1$  value of  
298 implemented model describing country traffic volume in 2018-2019 is -0.0002 for workdays and -  
299 0.02648 for holidays. These numbers are close to zero and confirm the hypothesis that the gasoline price  
300 change is the only factor influencing the changes in traffic volume. The results of the  $\beta_1$  values for  
301 nationwide traffic volume are presented in Table 5. It is shown that the  $\beta_1$  value for the 2019-2020 period  
302 is -0.1423 for working days and -0.2648 for holidays. These results show that the change in gasoline price  
303 has a more significant effect on the volume of holiday trips than on workday trips. Since most holiday  
304 trips have recreational purposes, this reduction was expected.

#### 305 **4.2. Provincial Traffic Volume Changes Results**

306 The traffic volume on the roads of different provinces in the country showed varying patterns. Although  
307 initial steps to select the best RDD model were not taken for provincial data, local traffic patterns were  
308 assumed to be similar to those of the entire country. Therefore, linear modeling was performed on  
309 provincial data based on holidays and workdays, and the findings are presented in Figure 4. In the upper  
310 part of Figure 4, the  $\beta_1$  values for the provinces of Iran are shown and the  $\beta_1$  value for the whole country  
311 in 2019-2020 is shown in the lower part of Figure 4 separately for workdays and holidays. However,  
312 analyzing light traffic volume data at the provincial level is more complex than at the national level since  
313 traffic may take different paths from their origin to their destination, leading to multiple counting of the

314 same trips. As a result, the  $\beta_1$  observations may be affected, and caution must be exercised when  
315 interpreting the results. This phenomenon may contribute to the positive  $\beta_1$  values observed in some  
316 provinces (e.g., Hormozgan) and negative values in others during workdays or holidays.

### 317 **4.3. Speed Distribution Changes Results**

318 In the previous sections of the article, it was mentioned that the statistical measures of the distribution  
319 would be used to study the effects of gasoline price change on driving speed distribution. For this  
320 purpose, mean hourly speed data was divided into two parts, 55 days before and 55 days after the change  
321 in gasoline price. Then, the probability of driving at each speed was examined. The results are shown in  
322 Figure 5 where red and blue colors correspond to the days before and after the intervention. Table 6  
323 represents the statistical measures of driving speed distribution. As can be seen from the data in Table 6,  
324 drivers have tended to reduce their driving speed as the gasoline price increases. Although, this reduction  
325 in mean speed is not significant.

326 Meanwhile, the number of vehicles moving in the optimal fuel-efficient speed range (50 to 70 km/h) was  
327 examined. According to the results, the probability that a vehicle would drive at the range of 50 to 70  
328 km/h was 21.7% ( $0.288 - 0.071 = 0.217$ ) before the change. After the price change, this probability  
329 increased to 23.3% ( $0.311 - 0.078 = 0.233$ ). As a result, the probability of vehicles traveling in the fuel-  
330 efficient speed range has increased by 7.4% ( $((23.3 - 21.7) / 21.7 = 0.074)$ ). It should be noted that no  
331 similar increase was observed in the previous year's speed data.

### 332 **4.4. Speeding Violation Percentage Changes Results**

333 As the final part, the effects of gasoline price change on the speeding violation percentage are  
334 investigated. Speed violation percentage is the number of vehicles that have exceeded the permitted speed  
335 divided by the total traffic in a specific period. Speeds are recorded by loop detectors and compared with  
336 the highest permitted speed on each road. Speed violation percentage change is examined only throughout  
337 the country. Performing a model similar to what was done for the traffic volume showed a decrease in the  
338 number of violations across the country. According to the output of the RDD model for workdays, the  $\beta_1$   
339 coefficient is -0.1655 and the  $\beta_1$  coefficient for holidays is -0.3066. Similar to the traffic volume, the  
340 speeding violation percentage on holidays has been more affected by the gasoline price change than the  
341 workdays.

## 342 **5. Discussion**

### 343 **5.1. Summary**

344 In this article, the effects of increasing gasoline price on the characteristics of people's travel and their  
345 driving behavior are investigated. The traffic volume has been selected and studied as an indicator of the  
346 trip length and trip count, as well as driving speed and the number of speeding violations as indicators of  
347 people's driving behavior. To study the effects, with the help of the Regression Discontinuity Design  
348 (RDD) method, daily traffic volume data of loop detectors on Iran's road network in two national and  
349 provincial scales were examined.

350 Also, due to the difference in people's behavior on different days of the week, experiments were  
351 conducted in two subgroups of working days and holidays to increase accuracy. According to RDD  
352 results, a significant decrease in traffic volume can be seen (the value of the  $\beta_1$  coefficient in the RDD  
353 model is -0.1423 for workdays and -0.2648 for holidays). RDD at the provincial level also showed a  
354 reduction (except for one case) in traffic volume. Also, the volume of unauthorized speeding violations

355 decreased according to RDD results (the  $\beta_1$  coefficient in the RDD model was equal to -0.1655 for  
356 workdays and -0.3066 for holidays). Statistical indicators of the average hourly speed distribution on the  
357 roads also assessed the speed of vehicles on the roads. Although there were no significant changes in the  
358 statistics according to the previous studies in the literature, the probability of vehicles traveling at a fuel-  
359 efficient speed (50 km/h to 70 km/h) increased by 7.4%. According to the results obtained, it can be said  
360 that the change in gasoline price, in addition to the overall effects that will have on various aspects of the  
361 lives of commuters, will also have effects in the field of transportation. These effects include a reduction  
362 in the volume of traffic and the number of speeding violations.

## 363 5.2. Future work

- 364 • The duration of leisure trips, which include most holidays, varies. Therefore, dividing the  
365 holiday interval into two parts, consecutive long and short holidays, can also show the effect  
366 of changing the price of gasoline on two different types of short-term and long-term leisure  
367 trips.
- 368 • The impacts of price change on different vehicle classes and geographical locations can be  
369 examined in another study.
- 370 • In this article, a general overview of vehicle speed distribution was investigated daily. A  
371 similar study can be performed for different parts of the day (AM and PM peak hours) to  
372 observe the changes with better resolution.
- 373 • Investigating the impacts of gasoline price on traffic volume in various provinces of Iran has  
374 revealed a general decline. However, certain provinces do not conform to this overall trend.  
375 Further research examining the influence of factors such as external traffic influx,  
376 commercial versus non-commercial gasoline-powered vehicles, and potential double-  
377 counting of vehicles en route to their destination, on the results of an RDD analysis, may  
378 provide insight into the variability observed in smaller regions like Hormozgan Province, as  
379 illustrated in Figure 4.
- 380 • While this study sheds light on the impact of gas price hikes on Class 1 vehicle drivers in  
381 terms of volume and speed violations, some future directions for research could further  
382 contribute to this topic. One potential avenue would be to conduct a similar RDD analysis  
383 comparing the post-gas price hike period (2020-2021) with two other periods: a pre-gas price  
384 hike (2019-2020) and a more distant past (2018-2019). This would allow examining whether  
385 the observed rebound in volume and speed violations is sustained or if it returns to its original  
386 level before the price hike.
- 387 • Moreover, it would be interesting to investigate the impact of alternative transportation means  
388 on drivers' behavior. Specifically, exploring how the provision of public transportation  
389 options could act as a buffer against gas price increases and prevent the transfer effect of the  
390 price difference to other goods and services. This could potentially lead to a better  
391 equilibrium for both the drivers and the overall transportation system.

588 *Table 5.  $\beta_1$  values for nationwide traffic volume*

|                 | <b>2018-2019</b> | <b>2019-2020</b> |
|-----------------|------------------|------------------|
| <b>Workdays</b> | -0.0002          | -0.1423          |
| <b>Holidays</b> | -0.0258          | -0.2648          |

589

590 *Table 6. Speed distribution statistical measures*

|                            | <b>Mean</b> | <b>Variance</b> | <b>Mode</b> | <b>Median</b> |
|----------------------------|-------------|-----------------|-------------|---------------|
| <b>Before price change</b> | 77.09       | 285.89          | 84          | 80            |
| <b>After price change</b>  | 75.98       | 286.73          | 81          | 78            |

591 **Biographies**

592 **Sepehr Saeidi** is a civil engineer. He received his BSc degree in civil engineering in 2021 from the Sharif  
593 University of Technology. He is currently an MSc student at the Department of Civil Engineering, Sharif  
594 University of Technology, Iran. His research interests are data analytics, machine learning, and deep  
595 learning algorithms and their applications across civil engineering disciplines or the intersection of civil  
596 and other research fields.

597 **Zahra Amini** is a Professor of Civil Engineering at the Department of Civil Engineering, Sharif  
598 University of Technology in Iran. She obtained her BSc, MSc, and Ph.D. degrees from the University of  
599 California, Berkeley, Berkeley, USA. Her research focuses on subjects such as Intelligent Transportation  
600 Systems, Smart Cities, Traffic Flow Theory, and Traffic Control Strategies within the field of  
601 transportation engineering.
