Process capability index;
Maximum likelihood estimator;
Biased estimator;
Unbiased estimator;
$C_{p}$;
$C_{p k}$.

#### Abstract

Comparison of quality for products (supplies and goods) is extremely important for manufacturers and consumers. Based on correct comparisons, manufacturers and consumers can find better suppliers to cooperate and better merchandise to purchase, respectively. Quality is often measured and compared by process capability indices, among which $C_{p}$ is very effective, simple to apply, and particularly useful for the first round of comparison. In practice, $C_{p}$ is unknown and should be estimated from observations. Let $\widehat{C_{p i}}$ denote the maximum likelihood estimator obtained from normal process, $\mathcal{X}_{i}$, with index value $C_{p i}, i=1,2$. If $\widehat{C_{p 1}}>(<) \widehat{C_{p 2}}$ is observed, we will conclude that $C_{p 1}>(<) C_{p 2}$ and decide that $\mathcal{X}_{1}$ is better (worse) than $\mathcal{X}_{2}$. Given a small and positive number, $\epsilon$, there is no need to make comparison when $(1-\epsilon) C_{p 2}<C_{p 1}<(1+\epsilon) C_{p 2}$ since $C_{p 1}$ is close to $C_{p 2}$. It is desirable to observe $\widehat{C_{p 1}}>\widehat{C_{p 2}}$ with high probability when $(1+\epsilon) C_{p^{2}}<C_{p 1}$ and with low probability when $(1-\epsilon) C_{p 2}>C_{p 1}$. Given $0<\epsilon_{1}, \epsilon_{2}<1$, based on the table constructed from $P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$, we demonstrate how to find the smallest sample size needed to ensure observing $\widehat{C_{p 1}}>\widehat{C_{p 2}}$ with probability greater than $1-\epsilon_{1}$ when $(1+\epsilon) C_{p 2}<C_{p 1}$ and smaller than $\epsilon_{2}$ when $(1-\epsilon) C_{p 2}>C_{p 1}$.

## 1. Introduction

In order to build up a good credit, producers have to make sure that their products meet customers' requests with high probability. Therefore, process capability analysis is, a necessity. Once a stable process is confirmed in phase I study, process capability analysis can then be designed to estimate the proportion of parts that meets engineering requirements in a stable production process. There are several ways for the purpose; a well-known summary quantitative measure is the process capability index. It is designed for industrial field for the purpose of process assessment and

[^0]improvement for suppliers and consumers; however, it is also used extensively in many different fields which include education [1] and medical science [2].

In the past decades, there have been varieties of innovative process capability indices. All of these indices were designed to evaluate the potential ability of processes to meet different kinds of requirements. But, as pointed out in [3], none of the new indices has surpassed $C_{p}$ and $C_{p k}$ in popularity or ease of use.

Kane [4] introduced index $C_{p}$ for the very first time defined as the fraction between the allowable range of measurements over which the process measurement can vary and the range of measurements in which the process is actually varying. It can be expressed as $C_{p}=\frac{\text { USL-LSL }}{6 \sigma}$, where USL and LSL are the upper and the lower specification limits, respectively, and $\sigma$ is the process standard deviation. The index was named differently by different authors. For example, Finley [5] used the term "capability potential index"
to which Montgomery [6] referred as process capability ratio. Notice that $C_{p}$ concerns only the spread of a process not the process mean at all. So, it provides valuable information only when the mean is on target. The index $C_{p}$ is particularly suitable when the independent data are from a normal distribution and it is meaningless to use it if the process is not under statistical control.

The index $C_{p}$ has been proved to be useful in automotive and manufacturing industries, among others. For instance, it has been applied to piston-rings for an automotive engine [6] and bolts used in bridge construction [7]. Applications to fan housing weight, roller width, exhaust valves, and acrylic coating can be found in [8]. Recent applications of $C_{p}$ include engine axle manufacturing process [9], yogurt production [10], and calibration [11,12], etc.

In practice, $C_{p}$ is rarely known and has to be estimated from sample. Most of the statistical research concerning $C_{p}$ focus on the standard inferences including point and interval estimations and test. For examples, the maximum likelihood estimator of $C_{p}$ was proposed by Kane [4], its moments were discussed in Kotz and Johnson [7], and its sampling distribution was investigated by Chan et al. [13], Chou and Owen [14], Chou et al. [15], and Li et al. [16]. It was further shown that the maximum likelihood estimator is biased, but it is asymptotically unbiased when the sample size is large enough (see [3,7,8,17] and references therein for more details). In this paper, we present a different and useful study for $C_{p}$ comparison to be described explicitly below.

It is not uncommon that different manufactories may have different qualities for the same product. It is important to recognize the better process, since the better process can serve the consumers better and the worse process can be investigated by the manufacturers for improvements.

Let $N\left(\mu_{1}, \sigma_{1}^{2}\right)$ and $N\left(\mu_{2}, \sigma_{2}^{2}\right)$ denote the distributions of measurements from two manufacturing processes $\mathcal{X}_{1}$ and $\mathcal{X}_{2}$ with potential capability indices $C_{p 1}=\frac{\mathrm{USL}-\mathrm{LSL}}{6 \sigma_{1}}$ and $C_{p 2}=\frac{\mathrm{USL}-\mathrm{LSL}}{6 \sigma_{2}}$, respectively. Note that we assume both process have the same upper and lower specification limits. Since it is desirable to have a $C_{p}$ as large as possible, process $\mathcal{X}_{1}$ is considered to be better (worse) than process $\mathcal{X}_{2}$ if $C_{p 1}>(<) C_{p 2}$.

Unfortunately, $C_{p 1}$ and $C_{p 2}$ are often unknown, and hence cannot be applied to make comparisons. In practice, $C_{p 1}$ and $C_{p 2}$ can be inferred from samples. Let $X_{11}, \cdots, X_{1 n}$ and $X_{21}, \cdots, X_{2 n}$ denote two independent samples from $N\left(\mu_{1}, \sigma_{1}^{2}\right)$ and $N\left(\mu_{2}, \sigma_{2}^{2}\right)$, respectively. Let $S_{1}^{2}=\frac{1}{n} \sum_{i=1}^{n}\left(X_{1 i}-\bar{X}_{1}\right)^{2}$ and $S_{2}^{2}=$ $\frac{1}{n} \sum_{i=1}^{n}\left(X_{2 i}-\bar{X}_{2}\right)^{2}$ denote the sample variances, where $\bar{X}_{1}=\frac{1}{n} \sum_{i=1}^{n} X_{1 i}$ and $\bar{X}_{2}=\frac{1}{n} \sum_{i=1}^{n} X_{2 i}$ are the sample means. Since $\bar{X}_{1}, S_{1}^{2}, \bar{X}_{2}$, and $S_{2}^{2}$ are maximum likelihood estimators of $\mu_{1}, \sigma_{1}^{2}, \mu_{2}$, and $\sigma_{2}^{2}$, respectively,
$\widehat{C_{p 1}}=\frac{\mathrm{USL}-\mathrm{LSL}}{6 S_{1}}$ and $\widehat{C_{p 2}}=\frac{\mathrm{USL}-\mathrm{LSL}}{6 S_{2}}$ are maximum likelihood estimators of $C_{p 1}=\frac{\text { USL-LSL }}{6 \sigma_{1}}$ and $C_{p 2}=$ $\frac{\text { USL-LSL }}{6 \sigma_{2}}$, respectively. See Hogg and Craig [18] for more details.

The purpose of this paper is to provide an efficient way to find the smallest sample sizes that can help choosing the better process between $\mathcal{X}_{1}$ and $\mathcal{X}_{2}$ based on $\widehat{C_{p 1}}$ and $\widehat{C_{p 2}}$. No such study can be found in the literatures, to the best of our knowledge.

Without loss of generality, assume that $\widehat{C_{p 1}}>\widehat{C_{p 2}}$ is observed; naturally we decide that $C_{p 1}>C_{p 2}$. We will judge this decision under three cases: $C_{p 1} \in M$, $C_{p 1} \in R$, and $C_{p 1} \in L$, where $L=\left(0,(1-\epsilon) C_{p 2}\right]$, $M=\left((1-\epsilon) C_{p 2},(1+\epsilon) C_{p 2}\right), R=\left[(1+\epsilon) C_{p 2}, \infty\right)$, and $\epsilon$ is a small positive number.

We treat $M$ as an indifferent zone, since $C_{p 1}$ is close to $C_{p 2}$ when $C_{p 1} \in M$, and there is no need to make comparisons between $\mathcal{X}_{1}$ and $\mathcal{X}_{2}$. In this case, any decision will be good.

If $C_{p 1} \in R$, then $C_{p 1}>C_{p 2}$ and our decision will be good if we observe $\widehat{C_{p 1}}>\widehat{C_{p 2}}$ with high probability. In other words, it is desirable to have large value of:

$$
\begin{equation*}
\min _{C_{p 1} \in R} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right) \tag{1}
\end{equation*}
$$

If $C_{p 1} \in L$, then $C_{p 1}<C_{p 2}$ and our decision will be good if we observe $\widehat{C_{p 1}}>\widehat{C_{p 2}}$ with low probability. Thus, it is desirable to have small value of:

$$
\begin{equation*}
\max _{C_{p 1} \in L} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right) \tag{2}
\end{equation*}
$$

We explain the maximum in Relation (1) and the minimum in Relation (2) as follows. Note that for fixed $n, P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$ is a function of $C_{p 1}$ and $C_{p 2}$ (see Appendix), denoted as $F\left(C_{p 1}, C_{p 2}\right)=P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$. The minimum value of $F$ over $\left\{\left(C_{p 1}, C_{p 2}\right) \mid C_{p 1}>(1+\right.$ $\left.\epsilon) C_{p 2}\right\}$ is denoted by:

$$
\min _{C_{p 1} \in R} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)
$$

The maximum value of $F$ over $\left\{\left(C_{p 1}, C_{p 2}\right) \mid C_{p 1}<(1-\right.$ $\left.\epsilon) C_{p 2}\right\}$ is denoted by:

$$
\max _{C_{p 1} \in L} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right) .
$$

Given two small positive numbers $\epsilon_{1}$ and $\epsilon_{2}$, we aim to find the smallest sample size to ensure:

$$
\begin{equation*}
\min _{C_{p 1} \in R} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)>1-\epsilon_{1} \tag{3}
\end{equation*}
$$

and the smallest sample size to achieve:

$$
\begin{equation*}
\max _{C_{p 1} \in L} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)<\epsilon_{2} \tag{4}
\end{equation*}
$$

The rest of this paper is organized as follows: in

Section 2, we will give the form of $P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$ and the proof can be found in the Appendix. In Section 3, illustrations of sample size determinations will be given via some examples. Some remarks concerning the statistical inferences are presented in Section 4. Future study is proposed in Section 5. Conclusions are provided in Section 6.

## 2. Derivation of probabilities

In order to find the smallest $n$ that achieves Relations (3) and (4), we need to evaluate $P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$. The proofs of the following results are given in Appendix:

$$
\begin{equation*}
P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)=\frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \int_{2 \alpha}^{\pi}(\sin t)^{n-2} d t \tag{5}
\end{equation*}
$$

where $\alpha=\tan ^{-1}\left(\sigma_{1} / \sigma_{2}\right)$. When $n=2 k+3$, where $k$ denotes any nonnegative integer, Eq. (5) implies that:

$$
\begin{array}{r}
P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)=\frac{\Gamma(2 k+2)}{2^{2 k+1}[\Gamma(k+1)]^{2}} \\
\cdot \sum_{i=0}^{k}(-1)^{i}\binom{k}{i} \frac{[\cos (2 \alpha)]^{2 i+1}+1}{2 i+1}, \tag{6}
\end{array}
$$

where $\cos 2 \alpha=\frac{\sigma_{2}^{2}-\sigma_{1}^{2}}{\sigma_{1}^{2}+\sigma_{2}^{2}}$. Moreover, when $n=2 k+2$ :

$$
\begin{align*}
& P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right) \\
&= \frac{\Gamma(2 k+1)}{2^{2 k}\left[\Gamma\left(\frac{2 k+1}{2}\right)\right]^{2}}\left\{\frac{(\sin 2 \alpha)^{2 k-1}(\cos 2 \alpha)}{2 k}\right. \\
&+\frac{2 k-1}{(2 k)(2 k-2)}(\sin 2 \alpha)^{2 k-3}(\cos 2 \alpha) \\
&+\frac{(2 k-1)(2 k-3)}{(2 k)(2 k-2)(2 k-4)}(\sin 2 \alpha)^{2 k-5}(\cos 2 \alpha) \\
&+\cdots+\frac{(2 k-1)(2 k-3) \cdots 3}{(2 k)(2 k-2)(2 k-4) \cdots 2}(\sin 2 \alpha)(\cos 2 \alpha) \\
&\left.+\frac{(2 k-1)(2 k-3) \cdots 3.1}{(2 k)(2 k-2)(2 k-4) \cdots 2}(\pi-2 \alpha)\right\} \tag{7}
\end{align*}
$$

where:

$$
\begin{aligned}
& \alpha=\tan ^{-1}\left(\sigma_{1} / \sigma_{2}\right), \sin 2 \alpha=\frac{2 \sigma_{1} \sigma_{2}}{\sigma_{1}^{2}+\sigma_{2}^{2}}, \\
& \cos 2 \alpha=\frac{\sigma_{2}^{2}-\sigma_{1}^{2}}{\sigma_{1}^{2}+\sigma_{2}^{2}} .
\end{aligned}
$$

Given $n$ and $\frac{\sigma_{2}}{\sigma_{1}}\left(\right.$ or $\frac{C_{p 1}}{C_{p 2}}$ ), Eqs. (6) and (7) can be calculated. To save the places, the results for $n \in$ $\{3, \cdots, 100\}$ and $\frac{C_{p 1}}{C_{p 2}} \in\{0.1,0.2, \cdots, 0.9,0.95,1,1.05$, $1.1,1.2, \cdots, 2\}$, are given in Tables 1 to 3 .

It is easy to see from Tables 1 to 3 that $P\left(\widehat{C_{p 1}}>\right.$ $\left.\widehat{C_{p 2}}\right)$ increases with $\frac{C_{p 1}}{C_{p 2}}$. Moreover, $P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$ increases (decreases) with $n$ if $\frac{C_{p 1}}{C_{p 2}}>(<) 1$. It should be noted that the rounding error produces many 0 in Table 1 and many 1 in Table 3. Each 0 represents a positive number less than 0.00001 , and each 1 represents a positive number between 1 and 0.99999 .

## 3. Illustrations

In this section, we explain how to use the above results to find the smallest sample sizes needed to make comparisons so as to achieve the predetermined bounds for probabilities (1) and (2).

Example 1: If $\epsilon=0.05$, then the indifferent zone defined in Section 1 is $M=\left[(1-\epsilon) C_{p 2},(1+\epsilon) C_{p 2}\right]=$ [ $0.95 C_{p 2}, 1.05 C_{p 2}$ ], and we treat two processes with $C_{p 1}$ and $C_{p 2}$ equally well when $C_{p 1} \in M$. Note that 0.95 and 1.05 are chosen for convenience; they can be replaced by other suitable positive numbers $u$ and $v$, such that $u<1$ and $v>1$.

If $C_{p 1} \in R=\left[1.05 C_{p 2}, \infty\right)$, then $C_{p 1}>C_{p 2}$ and we want $P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$ to be large. If $C_{p 1} \in L=$ $\left(0,0.95 C_{p 2}\right]$, then $C_{p 1}<C_{p 2}$ and we want $P\left(\widehat{C_{p 1}}>\right.$ $\left.\widehat{C_{p 2}}\right)$ to be small. For example, if 0.67 and 0.35 are considered large and small enough, respectively, then the problem becomes what sample size $n$ will ensure that:

$$
\begin{equation*}
\min _{C_{p 1} \in R} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)>0.67 \tag{8}
\end{equation*}
$$

and:

$$
\begin{equation*}
\max _{C_{p 1} \in L} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)<0.35 \tag{9}
\end{equation*}
$$

Note that 0.67 and 0.35 are chosen for convenience; they can be replaced by any number $\gamma$ and $\delta$, such that $0<\gamma<1,0<\delta<1$, and $\gamma$ and $\delta$ are close to 1 and 0 , respectively.

In order to achieve Relation (8), we need $n \geq 83$ by Table 2 (check the rows and columns corresponding to $n \geq 83$ and $\frac{C_{p 1}}{C_{p 2}} \geq 1.05$, respectively).

Moreover, Relation (9) is true if $n \geq 58$ according to Table 2 (check the rows and columns corresponding to $n \geq 58$ and $\frac{C_{p 1}}{C_{p 2}} \leq 0.95$, respectively).

Consequently, if $n \geq 83$, then Relations (8) and (9) will be held simultaneously.

Example 2: If $\epsilon=0.1$, then $R=\left[(1+\epsilon) C_{p 2}, \infty\right)=$ $\left[1.1 C_{p 2}, \infty\right)$ and $L=\left(0,(1-\epsilon) C_{p 2}\right]=\left(0,0.9 C_{p 2}\right]$. What sample size $n$ will ensure for Relations (8) and (9)?

In order to achieve Relation (8), we need $n \geq 23$ by Table 2 (check the rows and columns corresponding to $n \geq 23$ and $\frac{C_{p 1}}{C_{p 2}} \geq 1.1$, respectively).

Table 1. $P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$ for given $n$ when $\frac{C_{p 1}}{C_{p 2}} \in\{0.1, \cdots, 0.8\}$.

| 50 | 0.99734 | 0.99935 | 0.99985 | 0.99997 | 0.99999 | 1.00000 | 99 | 0.99996 | 1.00000 | 1.00000 | 1.00000 | 1.00000 | 1.00000 |
| 51 | 0.99756 | 0.99942 | 0.99987 | 0.99997 | 0.99999 | 1.00000 | 100 | 0.99996 | 1.00000 | 1.00000 | 1.00000 | 1.00000 | 1.00000 |

Moreover, Relation (9) is true if $n \geq 15$ according to Table 2 (check the rows and columns corresponding to $n \geq 15$ and $\frac{C_{p 1}}{C_{p 2}} \leq 0.9$, respectively).

Consequently, if $n \geq 23$, then Relations (8) and (9) will be held simultaneously.

Example 3: If $\epsilon=0.1$, what sample size $n$ will ensure that:

$$
\begin{equation*}
\min _{C_{p 1} \in R} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)>0.8 \tag{10}
\end{equation*}
$$

and:

$$
\begin{equation*}
\max _{C_{p 1} \in L} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)<0.25 ? \tag{11}
\end{equation*}
$$

In order to achieve Relation (10), we need $n \geq 80$ by Table 2 (check the rows and columns corresponding to $n \geq 80$ and $\frac{C_{p 1}}{C_{p 2}} \geq 1.1$, respectively) .

Moreover, Relation (11) is true if $n \geq 43$ according to Table 2 (check the rows and columns corresponding to $n \geq 43$ and $\frac{C_{p 1}}{C_{p 2}} \leq 0.9$, respectively).

Consequently, if $n \geq 80$, then Relations (10) and (11) will be held simultaneously.

Tables can be constructed by Eqs. (6) and (7) for other choices of $\epsilon, n$, and $\frac{C_{p 1}}{C_{p 2}}$; the smallest sample sizes can be found accordingly to satisfy Relations (3) and (4) for given $\epsilon_{1}$ and $\epsilon_{2}$.

In order to find the relation between $n$ and $\epsilon$, we provide Figures 1 and 2 constructed from Tables 1 to 3 . It is seen that $n$ is a decreasing function of $\epsilon$. Without any surprises, the reasons are as follows. For $C_{p 1} \in L \cup R=\left(0,(1-\epsilon) C_{p 2}\right] \cup\left[(1+\epsilon) C_{p 2}, \infty\right)$, increasing $\epsilon$ will increase $\left|C_{p 1}-C_{p 2}\right|$, thereby increase $\left|\widehat{C_{p 1}}-\widehat{C_{p 2}}\right|$, since $\widehat{C_{p 1}}$ and $\widehat{C_{p 2}}$ are close to $C_{p 1}$ and $C_{p 2}$, respectively. Large value of $\left|\widehat{C_{p 1}}-\widehat{C_{p 2}}\right|$ will make $\left\{\widehat{C_{p 1}}>\widehat{C_{p 2}}\right\}$ easy to observe when $C_{p 1} \in R$ and make $\left\{\widehat{C_{p 1}}>\widehat{C_{p 2}}\right\}$ hard to observe when $C_{p 1} \in L$. In other words, large $\epsilon$ correspond to small sample size $n$ needed to make $P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$ large when $C_{p 1} \in R$ and make $P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$ small when $C_{p 1} \in L$.

Figure 1. Smallest $n$ to ensure $\min _{C_{p 1} \in R} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)>p$ with $R=\left[(1+\epsilon) C_{p 2}, \infty\right)$.

Figure 2. Smallest $n$ to ensure $\max _{C_{p 1} \in L} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)<p$ with $L=\left(0,(1-\epsilon) C_{p 2}\right]$.

## 4. Remarks

In this section, we will discuss some connections between our method and confidence interval and unbiased estimators.

In addition to our comparison method, confidence intervals for $C_{p 1}-C_{p 2}$ can also be applied to make comparisons between $\widehat{C}_{p 1}$ and $\widehat{C}_{p 2}$. We will show that these two methods are equivalent when sample size is large. But, our method is better when sample size is small.

Our approach depends heavily on the maximum likelihood estimators of the standard deviations. Since the maximum likelihood estimators are biased, it is interesting to see the effects when the maximum likelihood estimators are replaced by some other unbiased estimators. We will show that estimators might make no difference for the comparisons.

First, we present the connection to confidence interval. When sample size $n$ is large, it is known by central limit theorem that $\widehat{C}_{p 1}$ and $\widehat{C}_{p 2}$ are asymptotically normally distributed as $N\left(C_{p 1}, \frac{1}{2 n} C_{p 1}^{2}\right)$ and $N\left(C_{p 2}, \frac{1}{2 n} C_{p 2}^{2}\right)$, respectively (see [19]). Therefore, $\widehat{C}_{p 1}-\widehat{C}_{p 2}$ is asymptotically normally distributed as $N\left(C_{p 1}-C_{p 2}, \frac{1}{2 n}\left[C_{p 1}^{2}+C_{p 2}^{2}\right]\right)$, since $\widehat{C}_{p 1}$ and $\widehat{C}_{p 2}$ are independent. Consequently, an approximately level $(1-\alpha) \%$ of confidence interval for $C_{p 1}-C_{p 2}$ is given as $[A, B]$, where:

$$
\begin{aligned}
& A=\widehat{C}_{p 1}-\widehat{C}_{p 2}-z_{\alpha / 2} \sqrt{\frac{\widehat{C}_{p 1}^{2}+\widehat{C}_{p 2}^{2}}{2 n}} \\
& B=\widehat{C}_{p 1}-\widehat{C}_{p 2}+z_{\alpha / 2} \sqrt{\frac{\widehat{C}_{p 1}^{2}+\widehat{C}_{p 2}^{2}}{2 n}}
\end{aligned}
$$

and $z_{\alpha / 2}$ satisfies $P\left(N(0,1) \geq z_{\alpha / 2}\right)=\alpha / 2$.
We conclude that $C_{p 1}>C_{p 2}$ when:

$$
\widehat{C}_{p 1}-\widehat{C}_{p 2}-z_{\alpha / 2} \sqrt{\frac{\widehat{C}_{p 1}^{2}+\widehat{C}_{p 2}^{2}}{2 n}}>0
$$

Thus, we want:

$$
P\left(\widehat{C}_{p 1}-\widehat{C}_{p 2}-z_{\alpha / 2} \sqrt{\frac{\widehat{C}_{p 1}^{2}+\widehat{C}_{p 2}^{2}}{2 n}}>0\right)
$$

to be large (small) when $C_{p 1}>(<) C_{p 2}$.
Similarly, we conclude that $C_{p 1}<C_{p 2}$ when:

$$
\widehat{C}_{p 1}-\widehat{C}_{p 2}+z_{\alpha / 2} \sqrt{\frac{\widehat{C}_{p 1}^{2}+\widehat{C}_{p 2}^{2}}{2 n}}<0
$$

Thus, we want:

$$
P\left(\widehat{C}_{p 1}-\widehat{C}_{p 2}+z_{\alpha / 2} \sqrt{\frac{\widehat{C}_{p 1}^{2}+\widehat{C}_{p 2}^{2}}{2 n}}<0\right)
$$

to be large (small) when $C p_{1}<(>) C p_{2}$.
When $n$ is large, $z_{\alpha / 2} \sqrt{\frac{\widehat{C}_{p 1}^{2}+\widehat{C}_{p 2}^{2}}{2 n}}$ is negligible, and confidence interval based comparison method needs $P\left(\widehat{C}_{p 1}-\widehat{C}_{p 2}>0\right)$ to be large (small) when $C_{p 1}>$ $(<) C_{p 2}$, equivalent to our method.

When sample size $n$ is small, it is not easy to find a confidence interval for $C_{p 1}-C_{p 2}$, since the distribution of $\widehat{C}_{p 1}-\widehat{C}_{p 2}$ is extremely complicated. Clearly, our method works well for small $n$, and hence better than confidence interval based comparison.

We proceed to present the connection to unbiased estimators. First, consider the unbiased estimator constructed from sample standard deviation. Let:

$$
\bar{S}_{j}=\frac{1}{c_{4}} \sqrt{\frac{\sum_{i=1}^{n}\left(X_{j i}-\bar{X}_{j}\right)^{2}}{(n-1)}}, \quad j=1,2
$$

where:

$$
c_{4}=\sqrt{\frac{2}{n-1}} \frac{\Gamma(n / 2)}{\Gamma((n-1) / 2)}
$$

Then, $\bar{S}_{j}$ is an unbiased estimator of $\sigma_{j}, j=1,2$ (see [20]). Define:

$$
\bar{C}_{p j}=\frac{\mathrm{USL}-\mathrm{LSL}}{6 \bar{S}_{j}}, \quad j=1,2
$$

Then:

$$
\begin{aligned}
P\left(\bar{C}_{p 1}>\bar{C}_{p 2}\right) & =P\left(\bar{S}_{2}>\bar{S}_{1}\right) \\
& =P\left(S_{2}>S_{1}\right)=P\left(\widehat{C}_{p 1}>\widehat{C}_{p 2}\right) .
\end{aligned}
$$

Consequently, the final comparisons results made by maximum likelihood estimators $S_{1}$ and $S_{2}$ will be the same as using unbiased estimators $\bar{S}_{1}$ and $\bar{S}_{2}$.

Sample range can also be modified to be unbiased estimator of the standard deviation. Define $X_{j(n)}=\max \left\{X_{j 1}, X_{j 2}, \cdots, X_{j n}\right\}$, and $X_{j(1)}=$
$\min \left\{X_{j 1}, X_{j 2}, \cdots, X_{j n}\right\}$, then $R_{j}=X_{j(n)}-X_{j(1)}$ denotes the sample range of $X_{j 1}, X_{j 2}, \cdots, X_{j n}, j=$ 1,2. Define:

$$
\tilde{S}_{j}=\frac{R_{j}}{d_{2}}
$$

where $d_{2}=\frac{\mathrm{ER}_{j}}{\sigma_{j}}$, then $\tilde{S}_{j}$ is an unbiased estimator of $\sigma_{j}, j=1,2$. Note that $d_{2}$ depends only on the sample size (see [20]). Define:

$$
\tilde{C}_{p j}=\frac{\mathrm{USL}-\mathrm{LSL}}{6 \tilde{S}_{j}}, \quad j=1,2
$$

Then:

$$
P\left(\tilde{C}_{p 1}>\tilde{C}_{p 2}\right)=P\left(\tilde{S}_{2}>\tilde{S}_{1}\right)=P\left(R_{2}>R_{1}\right)
$$

When sample size $n$ is large enough, $R_{j}$ will be close to $4 S_{j}$, denoted by $R_{j} \sim 4 S_{j}, j=1,2$. In this case:

$$
\begin{aligned}
P\left(\tilde{C}_{p 1}>\tilde{C}_{p 2}\right) & =P\left(R_{2}>R_{1}\right) \sim P\left(4 S_{2}>4 S_{1}\right) \\
& =P\left(S_{2}>S_{1}\right)=P\left(\widehat{C}_{p 1}>\widehat{C}_{p 2}\right) .
\end{aligned}
$$

Therefore, the final comparisons results produced by $S_{1}$ and $S_{2}$ will be close to those results made by $\tilde{S}_{1}$ and $\tilde{S}_{2}$.

However, when $R_{j}$ is not close to $4 S_{j}, j=1,2$, it is extremely difficult to calculate $P\left(R_{2}>R_{1}\right)$ and $P\left(\tilde{C}_{p 1}>\tilde{C}_{p 2}\right)$ exactly. The evaluation of $P\left(\tilde{C}_{p 1}>\right.$ $\tilde{C}_{p 2}$ ) and the subsequent work for comparison deserves a future research. More topics for future study are presented in the following section.

## 5. Future study

In this paper, we deal with one-dimensional process capability index $C_{p}$ comparisons based on maximum likelihood estimators constructed from two normal distributions. There are many ways to extend our findings. We point out below some directions for future research.

- Extension from $C_{p}$ comparison to $C_{p k}$ comparison: Let $\mu$ and $\sigma$ denote the process mean and standard deviation, respectively. The process capability index $C_{p k}$ is defined as $\frac{d-|\mu-M|}{3 \sigma}$ where $d=\frac{\text { USL-LSL }}{2}$ and $M=\frac{\mathrm{USL}+\mathrm{LSL}}{2}$. Index $C_{p k}$ was created to offset some of the weakness of $C_{p}$, primarily the fact that $C_{p}$ measured capability in terms of processvariation only and did not take process location into consideration [3]. Therefore, it is valuable to make $C_{p k}$ comparison when the mean values of the processes are off-target. Let $\widehat{C}_{p k 1}$ and $\widehat{C}_{p k 2}$ denote the maximum likelihood estimators of $C_{p k}$
obtained from two normal processes. The complex distribution of $\widehat{C}_{p k 1}-\widehat{C}_{p k 2}$ will make the evaluation of $P\left(\widehat{C}_{p k 1}-\widehat{C}_{p k 2}>0\right)$ extremely difficult. Numerical or simulation techniques may be helpful to solve this problem.
- Extension from $C_{p}$ comparison to multivariate $C_{p}$ comparison: Let $\boldsymbol{\mu}$ and $\boldsymbol{\Sigma}$ denote the process mean vector and variance-covariance matrix, respectively; and multivariate $C_{p}$ can be defined based on $|\boldsymbol{\Sigma}|$ or $\operatorname{tr} \boldsymbol{\Sigma}$, the determinant, and trace of $\boldsymbol{\Sigma}$, respectively. Based on observations sampled from multivariate normal distribution $N(\boldsymbol{\mu}, \boldsymbol{\Sigma})$, comparison can be based on $|\hat{\boldsymbol{\Sigma}}|$ or $\operatorname{tr} \hat{\boldsymbol{\Sigma}}$, where $\hat{\boldsymbol{\Sigma}}$ is the maximum likelihood estimator of $\boldsymbol{\Sigma}$. Multivariate $C_{p}$ comparison can be made based on many mathematical and statistical properties of $\hat{\boldsymbol{\Sigma}}$ provided in [21].

Multivariate $C_{p}$ can also be defined by:

$$
C_{p M}=\frac{\sum_{i=1}^{v}\left(\mathrm{USL}_{i}-\mathrm{LSL}_{i}\right)}{\sum_{i=1}^{v}\left(\mathrm{UPL}_{i}-\mathrm{LPL}_{i}\right)},
$$

where $\mathrm{USL}_{i}$ and $\mathrm{LSL}_{i}$ are the upper and lower specification limits for the $i$ th quality characteristic; $\mathrm{UPL}_{i}$ and $\mathrm{LPL}_{i}$ are the upper and lower specification limits of a modified process region for the $i$ th quality characteristic, $i=1, \cdots, v$ (see [22] for more details). In this case, we may need help from computer software since the mathematical framework is hard to deal with.

- Extension from normal process comparison to nonnormal process comparison: Non-normal observations are frequently found from many processes in industry, for instances, leukocyte filtering process [23] and manufacturing process [24], among others. If non-normal process can be transformed to normal via the Box-Cox transformation [25], then the $C_{p}$ comparison method for normal processes can be applied. If the Box-Cox transformation is not successful, we seek help from the definition of $C_{p}$ suitable for non-normal process. For example, quantile based $C_{P}$ definitions can be found in [2628], among others. However, the estimation of $C_{p}$ is then formed from quantile estimators. It is not easy to make inferences based on quantile estimators since the distributions involved are very complicated.
- Extension from two-process comparison to threeprocess comparison: Given maximum likelihood estimators $\widehat{C}_{p 1}, \widehat{C}_{p 2}$, and $\widehat{C}_{p 3}$ obtained from three normal processes, we can make three comparisons based on $\left\{\widehat{C}_{p 1}, \widehat{C}_{p 2}\right\},\left\{\widehat{C}_{p 1}, \widehat{C}_{p 3}\right\}$, and $\left\{\widehat{C}_{p 2}, \widehat{C}_{p 3}\right\}$, separately, from which conclusion can be made. Alternatively, we can also make one comparison based on $\widehat{C}_{p 1}, \widehat{C}_{p 2}$, and $\widehat{C}_{p 3}$ simultaneously. In this case, the calculation of $P\left(\widehat{C}_{p 1}>\widehat{C}_{p 2}>\widehat{C}_{p 3}\right)$
and the subsequent settings for comparison are straightforward and tedious.

## 6. Conclusions

Let $\mathcal{X}_{1}$ and $\mathcal{X}_{2}$ be two manufacturing processes with process capability indices $C_{p 1}=\frac{\mathrm{USL}-\mathrm{LSL}}{6 \sigma_{1}}$ and $C_{p 2}=$ $\frac{\text { USL-LSL }}{6 \sigma_{2}}$, respectively. Let $\widehat{C_{p 1}}$ and $\widehat{C_{p 2}}$ denote the maximum likelihood estimators of $C_{p 1}$ and $C_{p 2}$ under the normality assumption. We calculate $P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$ and present a table from which smallest sample sizes can be determined to make $\min _{C_{p 1} \in R} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$ large and make $\max _{C_{p 1} \in L} P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right)$ small, where $L=\left(0,(1-\epsilon) C_{p 2}\right], R=\left[(1+\epsilon) C_{p 2}, \infty\right)$, and $\epsilon>0$. Consequently, comparison of $C_{p 1}$ and $C_{p 2}$ based on $\widehat{C_{p 1}}$ and $\widehat{C_{p 2}}$ provide manufacturers and consumers a way to correctly (wrongly) recognize better suppliers to cooporate and better merchandise to purchase, respectively, with high (low) probability. We discuss statistical properties concerning our method. We also point out some directions for future study.

## Acknowledgments

The authors appreciate Editor-in-Chief and referees for their valuable comments. According to referees' recommendations, Sections 4 and 5 are created thereby broadening the contributions of this paper.

## Appendix

Here, we calculate Eqs. (5), (6), and (7) stated in Section 2. First note that $\frac{S_{2}^{2} \sigma_{1}^{2}}{S_{1}^{2} \sigma_{2}^{2}}$ has an $F$ distribution, $F(n-1, n-1)$, with probability density function:

$$
\begin{equation*}
\frac{\Gamma(n-1)}{\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \frac{w^{(n-3) / 2}}{(1+w)^{n-1}}, \quad 0<w<\infty \tag{A.1}
\end{equation*}
$$

(see [18]).
In view of Relation (A.1) with the transformations $w=(\tan \theta)^{2}$ and $t=2 \theta$, we have:

$$
\begin{aligned}
& P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right) \\
& =P\left(S_{2}^{2}>S_{1}^{2}\right) \\
& =P\left(\frac{S_{2}^{2} \sigma_{1}^{2}}{S_{1}^{2} \sigma_{2}^{2}}>\frac{\sigma_{1}^{2}}{\sigma_{2}^{2}}\right) \\
& =P\left(F_{n-1, n-1}>\frac{\sigma_{1}^{2}}{\sigma_{2}^{2}}\right) \\
& =\int_{\sigma_{1}^{2} / \sigma_{2}^{2}}^{\infty} \frac{\Gamma(n-1)}{\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \frac{w^{(n-3) / 2}}{(1+w)^{n-1}} d w \\
& =\int_{\alpha}^{\pi / 2} \frac{\Gamma(n-1)}{\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \frac{\left[(\tan \theta)^{2}\right]^{(n-3) / 2}}{\left[1+(\tan \theta)^{2}\right]^{n-1}} \cdot[2 \tan \theta][\sec \theta]^{2} d \theta \\
& =\frac{2 \Gamma(n-1)}{\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \int_{\alpha}^{\pi / 2} \frac{(\tan \theta)^{n-2}}{(\sec \theta)^{2 n-4}} d \theta \\
& =\frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \int_{2 \alpha}^{\pi}(\sin t)^{n-2} d t,
\end{aligned}
$$

where $\alpha=\tan ^{-1}\left(\sigma_{1} / \sigma_{2}\right)$, and Eq. (5) follows.

We will calculate Eq. (5) further for $n=2 k+3$ and $n=2 k+2$ separately, where $k \in\{0,1,2, \cdots\}$. Consider the case when $n=2 k+3$. To show Eq. (6), combine Eq. (5), the transformation $u=\cos t$, and binomial theorem together to imply that:

$$
\begin{aligned}
& P\left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right) \\
&=\frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \int_{2 \alpha}^{\pi}(\sin t)^{n-2} d t \\
&=\frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \int_{2 \alpha}^{\pi}(\sin t)^{2 k+1} d t \\
&=\frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \int_{-1}^{\cos (2 \alpha)}\left(1-u^{2}\right)^{k} d u \\
&=\frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \cdot \int_{-1}^{\cos (2 \alpha)} \sum_{i=0}^{k}\binom{k}{i}\left(-u^{2}\right)^{i} d u \\
&=\frac{\Gamma(2 k+2)}{2^{2 k+1}[\Gamma(k+1)]^{2}} \\
& . \sum_{i=0}^{k}(-1)^{i}\binom{k}{i} \frac{[\cos (2 \alpha)]^{2 i+1}+1}{2 i+1}
\end{aligned}
$$

where $\cos (2 \alpha)=\frac{\sigma_{2}^{2}-\sigma_{1}^{2}}{\sigma_{1}^{2}+\sigma_{2}^{2}}$, as was shown.
We proceed to calculate Eq. (5) with $n=2 k+2$ and verify Eq. (7). First note that integration by parts implies:

$$
\begin{align*}
\int(\sin t)^{m} d t= & -\frac{(\sin t)^{m-1}(\cos t)}{m} \\
& +\frac{m-1}{m} \int(\sin t)^{m-2} d t \tag{A.2}
\end{align*}
$$

where $m \geq 2$ is a positive integer. Applying Eq. (A.2) several times, we have:

$$
\begin{aligned}
P & \left(\widehat{C_{p 1}}>\widehat{C_{p 2}}\right) \\
& =\frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \int_{2 \alpha}^{\pi}(\sin t)^{n-2} d t \\
& =\frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}} \int_{2 \alpha}^{\pi}(\sin t)^{2 k} d t \\
& =\frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}}\left[\frac{(\sin 2 \alpha)^{2 k-1}(\cos 2 \alpha)}{2 k}\right.
\end{aligned}
$$

$$
\left.\begin{array}{rl} 
& \left.+\frac{2 k-1}{2 k} \int_{2 \alpha}^{\pi}(\sin t)^{2 k-2} d t\right] \\
= & \frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}}\left\{\frac{(\sin 2 \alpha)^{2 k-1}(\cos 2 \alpha)}{2 k}\right. \\
& +\frac{2 k-1}{(2 k)(2 k-2)}(\sin 2 \alpha)^{2 k-3}(\cos 2 \alpha) \\
& \left.+\frac{(2 k-1)(2 k-3)}{(2 k)(2 k-2)} \int_{2 \alpha}^{\pi}(\sin t)^{2 k-4} d t\right\} \\
= & \frac{\Gamma(n-1)}{2^{n-2}\left[\Gamma\left(\frac{n-1}{2}\right)\right]^{2}}\left\{\frac{(\sin 2 \alpha)^{2 k-1}(\cos 2 \alpha)}{2 k}\right. \\
& +\frac{2 k-1}{(2 k)(2 k-2)}(\sin 2 \alpha)^{2 k-3}(\cos 2 \alpha) \\
& +\frac{(2 k-1)(2 k-3)}{(2 k)(2 k-2)(2 k-4)}(\sin 2 \alpha)^{2 k-5}(\cos 2 \alpha)+\cdots \\
& +\frac{(2 k-1)(2 k-3) \cdots 3}{(2 k)(2 k-2)(2 k-4) \cdots 2}(\sin 2 \alpha)(\cos 2 \alpha) \\
& \left.+\frac{(2 k-1)(2 k-3) \cdots 3.1}{(2 k)(2 k-2)(2 k-4) \cdots 2}(\pi-2 \alpha)\right\} \\
& \left.+\frac{(2 k-1)(2 k-3) \cdots 3.1}{(2 k)(2 k-2)(2 k-4) \cdots 2}\left(\int_{2 \alpha}^{\pi} 1 d t\right)\right\} \\
& +\frac{\Gamma(2 k+1)}{(2 k)(2 k-2)}(\sin 2 \alpha)^{2 k-3}(\cos 2 \alpha) \\
& +\frac{(2 k-1)(2 k-3)}{(2 k)(2 k-2)(2 k-4)}(\sin 2 \alpha)^{2 k-5}(\cos 2 \alpha)+\cdots \\
& (\sin 2 \alpha)^{2 k-1}(\cos 2 \alpha) \\
2 k
\end{array}\right)
$$

where $\alpha=\tan ^{-1}\left(\sigma_{1} / \sigma_{2}\right), \sin 2 \alpha=\frac{2 \sigma_{1} \sigma_{2}}{\sigma_{1}^{2}+\sigma_{2}^{2}}$, and $\cos 2 \alpha=$ $\frac{\sigma_{2}^{2}-\sigma_{1}^{2}}{\sigma_{1}^{2}+\sigma_{2}^{2}}$. The verification is completed.

## Biographies

Sy-Mien Chen received her PhD degree from Department of Mathematics, University of Maryland at College Park, in 1990. She is currently an Associate Professor at Department of Mathematics, Fu-Jen

Catholic University, Taiwan. Her research interests are statistics and statistical quality control. Her papers are mainly published at Statistics, Journal of Nonparametric Statistics, Communication in Statistics, and Fu-Jen Studies.

Jian-Tong Liaw received his PhD from Institute tute of Applied Science and Engineering, Fu-Jen Catholic University in 2008. He is currently an Assistant Professor at Fu-Jen Catholic University, Taiwan. His research interests are statistics and its applications and computational statistics. He has published papers at

Statistics, Fu-Jen Studies, and Journal of Probability, and Statistical Science.

Yu-Sheng Hsu received his PhD degree from Department of Statistics, Rutgers University, in 1990. He is currently an Associate Professor at Department of Mathematics, National Central University, Taiwan. His research fields include statistics and its applications. He has published papers at Statistics, Journal of Nonparametric Statistics, Communication in Statistics, IEEE Sensors Journal, and IEEE Transactions on Antennas and Propagation.
